

Package ‘MutSeqR’

June 13, 2025

Title Analysis of Error-Corrected Sequencing Data for Mutation Detection

Version 0.99.0

Description Standard methods for analysis of mutation data following error-corrected sequencing (ECS) for the purpose of mutagenicity assessment. Functions include importing the mutation lists provided by a variant caller, and a set of analytical tools for statistical testing and visualization of mutation data; comparison to COSMIC and/or germline signatures; etc.

annotate_cpg_sites	<i>Annotate CpG sites</i>
--------------------	---------------------------

Description

A simple method to test whether your trinucleotide context contains a CpG site. Vectorized version of Biostrings::vcountPattern is used.

Usage

```
annotate_cpg_sites(mutation_data, motif = "CG", column_query = "context", ...)
```

Arguments

mutation_data	A dataframe or GRanges object containing the genomic regions of interest in which to look for CpG sites.
motif	Default "CG", which returns CpG sites. You could in theory use an arbitrary string to look at different motifs. Use with caution. In this case the pattern being searched must be a column in the mutation data.
column_query	Default "context" but can be any column in the mutation data that you wish to look for a motif in.
...	Additional arguments to vcountPattern()

Value

A data frame with the same number of rows as there were ranges in the input, but with an additional metadata column indicating CpG sites in the target sequence of the mutation.

bmd_proast	<i>BMD modeling using PROAST</i>
------------	----------------------------------

Description

Calculate the benchmark dose (BMD) of continuous, individual-level data with optional model averaging. This function is intended to model the dose-response of mutation frequency. This function is an extension of the PROAST software (copyright RIVM National Institute for Public Health and the Environment).

Usage

```

bmd_proast(
  mf_data,
  dose_col = "dose",
  response_col = "mf_min",
  covariate_col = NULL,
  bmr = 0.5,
  adjust_bmr_to_group_sd = FALSE,
  model_averaging = TRUE,
  num_bootstraps = 200,
  plot_results = FALSE,
  output_path = NULL,
  raw_results = FALSE
)

```

Arguments

<code>mf_data</code>	A data frame containing the data to be analyzed. Data should be individual for each sample. Required columns are the column containing the dose <code>dose_col</code> the column(s) containing the mutation frequency <code>response_col</code> , and the column containing the covariate <code>covariate_col</code> , if applicable.
<code>dose_col</code>	The column in <code>mf_data</code> containing the dose data. Values must be numeric. Default is "dose".
<code>response_col</code>	The column(s) in <code>mf_data</code> containing the mutation frequency. Multiple <code>response_cols</code> can be provided. Default is "mf_min".
<code>covariate_col</code>	The column in <code>mf_data</code> containing the covariate. If no covariate is present, set to NULL (default).
<code>bmr</code>	The Benchmark Response value. The BMR is defined as a <code>bmr</code> -percent change in mean response relative to the controls. Default is 0.5 (50% change).
<code>adjust_bmr_to_group_sd</code>	A logical value indicating whether the group standard deviation should be used as the BMR. If TRUE, the BMR will be bet set to one standard deviation above the control group mean. Default is FALSE.
<code>model_averaging</code>	A logical value indicating whether confidence intervals should be calculated using model averaging. Default is TRUE (recommended).
<code>num_bootstraps</code>	The number of bootstrap resamples to be used in the model averaging. Default is 200 (recommended).
<code>plot_results</code>	A logical value indicating whether to plot the BMD models and/or the Cleveland plots. Default is FALSE. Plots may be exported directly to an <code>output_path</code> , or returned within a list to the user.
<code>output_path</code>	The file path indicating where to save the plots. If NULL, the plots will automatically be displayed to the graphics window and then returned as a list alongside the bmd results.
<code>raw_results</code>	A logical value indicating whether to return the raw results from the PROAST analysis. If FALSE, data is returned as a summary table.

Details

This function is a modified version of the original interactive PROAST software (<https://www.rivm.nl/en/proast>) that allows for batch processing of data. The function is designed to be used with the output of `calculate_mf` for the purpose of calculating the Benchmark Dose of mutation frequency data. As such, some functionality of the original PROAST software has been removed.

This function will accept continuous data, with an observation for each individual subject. It is assumed that data are lognormally distributed. The response data is log-transformed, then back-transformed after the statistical analysis. The function will fit model 3 or 5 from various families of models (Exponential, Hill, Inverse Exponential, LogNormal). It will then compare the fits of models 3 and 5 for each model family and select the model with the lowest AIC. The BMD 90% confidence intervals will be calculated based on the selected model (3 or 5) for each model family using the profile likelihood method. The BMD 90% confidence interval may also be calculated using the bootstrap method if `model_averaging = TRUE`. It is recommended to use 200 bootstraps for model averaging.

To replicate these results in the PROAST interactive software, select the following menu options:

1. `f.proast(mf_data)`
2. What type of response data do you want to consider? *1: continuous, individual data*
3. Do you want to fit a single model or fit various nested families of models? *3: select model 3 or 5 from various families of models*
4. Q1: Which variable do you want to consider as the independent variable? *# : dose_col*
5. Give number(s) of the response(s) you want to analyse. *# : response_col*
6. Give number of factor serving as potential covariate (e.g.sex) type 0 if none. *# : covariate_col*
7. Do you want to adjust CES to within group SD? *1: no, 2: yes | adjust_bmr_to_group_sd: FALSE/TRUE*
8. Give value for CES (always positive) type 0 to avoid calculation of CIs. *bmr*
9. Do you want to calculate the BMD confidence interval by model averaging? *1: no 2: yes | model_averaging: FALSE/TRUE*
10. give number of bootstrap runs for calculating BMD confidence interval based on MA (e.g. 200) *num_bootstraps*
11. Which models do you want to be fitted? *4 : previous option with lognormal DR model added*

Value

A summary data frame of final results. If plots or raw results are selected, all data will be returned within a list.

The summary will include the following for each response variable and covariate subgroup (if applicable):

- Model: The m3 or m5 model selected for each model family (Exponential, Hill, Inverse Exponential, LogNormal).
- Response: The response variable.
- Covariate: The covariate subgroup, if applicable.
- bmr: The specified Benchmark Response.

- BMD: The Benchmark Dose, in original dose units, estimated for the given model.
- BMDL: The lower bound of the 90% confidence interval for the BMD, calculated by the profile likelihood method.
- BMDU: The upper bound of the 90% confidence interval for the BMD, calculated by the profile likelihood method.
- AIC: The Akaike Information Criterion for the selected model. Lower values indicate a better fit. It is advised to choose the BMD value from the model with the lowest AIC.
- weights: The weight of the model in the model averaging process, if applicable.
- Model averaging: The BMDL and BMDU calculated by the bootstrap method if `model_averaging = TRUE`.

If there is no significant response in the data, the function will return an empty data frame.

If `plot_results = TRUE` the function will create the following plots for each response variable. The plots will be saved to the `output_path`. If no `output_path` is provided, then they will be returned within a list alongside the summary data frame.

- Model Plots. The following plot will be created for each model family (Exponential, Hill, Inverse Exponential, LogNormal): The fitted curve of the selected (3 or 5) model. Data is log-transformed. Individual data points are plotted using small triangles. The geometric mean (median) at each dose is plotted as a large triangle. The BMD is indicated by the dotted line. If applicable, the covariate subgroup is indicated by color.
- `bootstrap_curves` If `model_averaging = TRUE`, the bootstrap curves based on model averaging. The geometric mean (median) at each dose is plotted as a large triangle. Data is log-transformed.
- `cleveland` plot if `model_averaging = TRUE` The BMD estimate for each model is plotted as a red point alongside the 90% confidence intervals. The size of the BMD point represents the model weight assigned during model averaging, based on the AIC.

If `raw_results = TRUE`, the function will return the raw results of the PROAST analysis alongside the summary data frame. PROAST `raw_results` is a list of variables and data that is continuously modified as it is passed through the `proast` functions. It can be given to `f.proast()` to resume analysis.

Examples

```
# Calculate the BMD for a 50% increase in mutation frequency from control
# With Model averaging.
# For the purpose of this example, num_bootstraps is set to 5 to reduce
# run time. 200 bootstraps is recommended.
example_file <- system.file("extdata", "Example_files",
                             "example_mutation_data_filtered.rds",
                             package = "MutSeqR")
example_data <- readRDS(example_file)
mf <- calculate_mf(example_data, retain_metadata_cols = "dose")
bmd <- bmd_proast(mf_data = mf,
                  dose_col = "dose",
                  response_col = c("mf_min", "mf_max"),
                  bmr = 0.5,
                  model_averaging = TRUE,
                  num_bootstraps = 5)
```

```
# Plot the Model Averaging 90% CI using plot_ci()
plot_df <- bmd %>%
  dplyr::filter(Model == "Model averaging") %>%
  dplyr::select(Response, BMD, BMDL, BMDU)
plot <- plot_ci(plot_df, order = "asc", log_scale = FALSE)
```

bmd_toxicr

BMD modeling using ToxicR

Description

Calculate the benchmark dose (BMD) for continuous dose-response data with optional model averaging. This function is intended to model the dose-response of mutation frequency using the ToxicR software.

Usage

```
bmd_toxicr(
  mf_data,
  data_type = "individual",
  dose_col = "dose",
  response_col = c("mf_min", "mf_max"),
  sd_col = NULL,
  n_col = NULL,
  bmr_type = "rel",
  bmr = 0.5,
  model = "exp-aerts",
  alpha = 0.05,
  model_averaging = TRUE,
  plot_results = FALSE,
  ma_summary = FALSE,
  output_path = NULL,
  ...
)
```

Arguments

mf_data	A data frame containing the dose-response data. Data may be individual for each sample or averaged over dose groups. Required columns for individual data are the column containing the dose dose_col and the column(s) containing the mutation frequency data response_col(s). Summary data must include the dose_col, the response_col(s) containing the mean response for each dose group, the sd_col containing the standard deviation of the response data, and the n_col containing the sample size for each dose group.
data_type	A string specifying the type of response data. Data may be response per individual or summarised across dose groups. Options are ("individual", "summary"). Default is "individual".

dose_col	The column in mf_data containing the dose data. Values must be numeric. Default is "dose".
response_col	The column(s) in mf_data containing the mutation frequency data. For summarised data types, this should be the mean response for each dose group. Multiple response_cols can be provided.
sd_col	The column in mf_data containing the standard deviation of the summarised response data. This is only required for data_type = "summary". If multiple response columns are provided, multiple sd_cols should be provided in the same order. Default is NULL.
n_col	The column in mf_data containing the sample size of each dose group. This is only required for data_type = "summary". If multiple response columns are provided, multiple n_cols should be provided in the same order. Default is NULL.
bmr_type	The type of benchmark response. Options are: "rel", "sd", "hybrid", "abs". Default is "rel". See details for more information.
bmr	A numeric value specifying the benchmark response. The bmr is defined in relation to the calculation requested in bmr_type. Default is 0.5.
model	The model type to use. Options are "all" or a vector of model types. Default is "exp-aerts", the Exponential model. See details for available models. Note that model averaging will use a pre-defined model set. See details for more information.
alpha	The specified nominal coverage rate for computation of the lower and upper confidence intervals for the benchmark dose (BMDL, BMDU). The confidence level is calculated as $100 \times (1 - 2\alpha)\%$. The default is 0.05 (90% CI).
model_averaging	A logical value indicating whether to use model averaging. Default is TRUE (recommended).
plot_results	A logical value indicating whether to plot the BMD models and/or the Cleveland plots. Default is FALSE. If TRUE, the function will save plots to the output_path or return them as a list alongside the summary of the results.
ma_summary	A logical value indicating whether to return the summary of the model averaging results. Default is FALSE.
output_path	The file path indicating where to save the plots. If NULL, the plots will automatically be returned as a list alongside the bmd results.
...	Additional arguments to be passed to the model fitting function. For more information, see single_continuous_fit or ma_continuous_fit if model averaging.

Details

Available model types for single model fitting are:

- "exp-aerts": $f(x) = a(1 + (c - 1)(1 - \exp(-bx^d)))$
- "invexp-aerts": $f(x) = a(1 + (c - 1)(\exp(-bx^{-d})))$
- "gamma-aerts": $f(x) = a(1 + (c - 1)(\text{Gamma}(bx^d; xi)))$
- "invgamma-aerts": $f(x) = a(1 + (c - 1)(1 - \text{Gamma}(bx^{-d}; xi)))$

- "hill-aerts": $f(x) = a(1 + (c - 1)(1 - \frac{b^d}{b^d + x^d}))$
- "lomax-aerts": $f(x) = a \left\{ 1 + (c - 1)(1 - \left(\frac{b}{b + x^d}\right)^\xi) \right\}$
- "invlomax-aerts": $f(x) = a \left\{ 1 + (c - 1)\left(\frac{b}{b + x^d}\right)^\xi \right\}$
- "lognormal-aerts": $f(x) = a \{ 1 + (c - 1)(\Phi(\ln(b) + d \times \ln(x))) \}$
- "logskew-aerts": $f(x) = a \{ 1 + (c - 1)(\Phi_{SN}(\ln(b) + d \times \ln(x); \xi)) \}$
- "invlogskew-aerts": $f(x) = a \{ 1 + (c - 1)(1 - \Phi_{SN}(\ln(b) - d \times \ln(x); \xi)) \}$
- "logistic-aerts": $f(x) = \frac{c}{1 + \exp(-a - b \times x^d)}$
- "probit-aerts": $f(x) = c(\Phi(a + b \times x^d))$
- "LMS": $f(x) = a(1 + (c - 1)(1 - \exp(-bx - dx^2)))$
- "gamma-efsa": $f(x) = a(1 + (c - 1)(\text{Gamma}(bx; d)))$

Here: $\Phi(\cdot)$ is the standard normal distribution and $\Phi_{SN}(\cdot; \cdot)$ is the skew-normal distribution. See [single_continuous_fit](#) for more details.

Model averaging is done over the the model set described in The European Food Safety Authority's (2022) Guidance on the use of the benchmark dose approach in risk assessment. These models are (normal then lognormal for each model): exp-aerts, invexp-aerts, hill-aerts, lognormal-aerts, gamma-efsa, LMS, probit-aerts, and logistic-aerts. See [ma_continuous_fit](#) for more details.

BMR types for continuous models:

- Relative deviation (default; `bmr_type = "rel"`). This defines the BMD as the dose that changes the control mean/median a certain percentage from the background dose. It is the dose that solves $|f(dose) - f(0)| = (1 \pm BMR)f(0)$
- Standard deviation (`bmr_type = "sd"`). This defines the BMD as the dose associated with the mean/median changing a specified number of standard deviations from the mean at the control dose. It is the dose that solves $|f(dose) - f(0)| = BMR \times \sigma$
- Absolute deviation (`bmr_type = "abs"`). This defines the BMD as an absolute change from the control dose of zero by a specified amount. That is the BMD is the dose that solves the equation $|f(dose) - f(0)| = BMR$.
- Hybrid deviation (`bmr_type = "hybrid"`). This defines the BMD that changes the probability of an adverse event by a stated amount relative to no exposure (i.e 0). That is, it is the dose that solves $\frac{Pr(X > x|dose) - Pr(X > x|0)}{Pr(X < x|0)} = BMR$. For this definition, $Pr(X < x|0) = 1 - Pr(X > X|0) = \pi_0$, where $0 \leq \pi_0 < 1$ is defined by the user as "point_p," and it defaults to 0.01. Note: this discussion assumed increasing data. The fitter determines the direction of the data and inverts the probability statements for decreasing data.

Value

If `model_averaging = FALSE`, the function returns a data frame with the BMD values and the $100 \times (1 - 2\alpha)\%$ confidence intervals (BMDL, BMDU) for each response column and each model listed. The AIC value is calculated for each model to compare fits. The AIC is calculated as maximum likelihood + $2 \times$ degrees of freedom.

If `model_averaging = TRUE`, the function returns a data frame with the BMD values and the $100 \times (1 - 2\alpha)\%$ confidence intervals (BMDL, BMDU) for each response column calculated using model

averaging. If `ma_summary = TRUE`, the function will return the posterior probabilities used in the model averaging.

If `plot_results = TRUE`, the function will plot the fitted models or the model averaged model to the data. When mode averaging, the function will also make a Cleveland plot, saved to the `output_path`. Here, the BMDs are plotted for each model in the set alongside the model averaged BMD. The BMD is represented by a red dot. The size of the dot is scaled on the model probability with the Model Average having a value of 100%. The BMDL and BMDU are expressed as interval bars. Plots may be automatically exported to an `output_path`. Alternatively, if `output_path = NULL`, the function will return a list that includes summary (the data frame containing the BMD results), and all generated plots.

Examples

```
# Calculate the BMD for a 50% increase in mutation frequency from control
# Individual data with Model averaging.
example_file <- system.file("extdata", "Example_files",
                             "example_mutation_data_filtered.rds",
                             package = "MutSeqR")
example_data <- readRDS(example_file)
mf <- calculate_mf(example_data, retain_metadata_cols = "dose")
bmd <- bmd_toxicr(mf_data = mf,
                  dose_col = "dose",
                  response_col = c("mf_min", "mf_max"))
# Plot the results using plot_ci()
plot <- plot_ci(bmd, order = "asc", log_scale = FALSE)

# Summary data with Model averaging.
mf_sum <- mf %>%
  dplyr::group_by(dose) %>%
  dplyr::summarise(mean_mf_min = mean(mf_min),
                   sd_min = sd(mf_min),
                   n_min = dplyr::n(),
                   mean_mf_max = mean(mf_max),
                   sd_max = sd(mf_max),
                   n_max = dplyr::n())
bmd <- bmd_toxicr(mf_data = mf_sum,
                  data_type = "summary",
                  dose_col = "dose",
                  response_col = c("mean_mf_min", "mean_mf_max"),
                  sd_col = c("sd_min", "sd_max"),
                  n_col = c("n_min", "n_max"))
```

calculate_mf

Calculate mutation frequency

Description

Calculates the mutation frequency for arbitrary groupings and creates a new dataframe with the results. Mutation frequency is # mutations / total bases, but this can be subset in different ways:

e.g., by mutation context. In this case, it is necessary to change the denominator of total bases to reflect the sequencing depth at the proper reference bases under consideration. Additionally, by default, the operation is run by default using both the minimum and maximum independent methods for counting mutations.

Usage

```
calculate_mf(
  mutation_data,
  cols_to_group = "sample",
  subtype_resolution = "none",
  variant_types = c("snv", "deletion", "insertion", "complex", "mnv", "sv", "ambiguous",
    "uncategorized"),
  calculate_depth = TRUE,
  precalc_depth_data = NULL,
  d_sep = "\t",
  summary = TRUE,
  retain_metadata_cols = NULL
)
```

Arguments

mutation_data The data frame to be processed containing mutation data. Required columns are listed below. Synonymous names for these columns are accepted.

- **contig:** The reference sequence name.
- **start:** 1-based start position of the feature.
- **alt_depth:** The read depth supporting the alternate allele.
- **variation_type:** The category to which this variant is assigned.
- **subtype_col:** The column containing the mutation subtype. This column depends on the `subtype_resolution` parameter.
- **reference context:** The column containing the reference base(s) for the mutation. This column depends on the `subtype_resolution` parameter.
- **cols to group:** all columns across which you want to calculate the mutation frequency. Ex. `c("tissue", "dose")`. These columns should be listed in `cols_to_group`.

It is also required to include the `total_depth` column if you are calculating depth from the mutation data. If you are using precalculated depth data, the `total_depth` column is not required.

cols_to_group A vector of grouping variables: this should be the groups of interest that you want to calculate a frequency for. For instance, getting the frequency by sample. Other options might include dose, locus, or `c("sample", "locus")`. All listed variables must be a column in the `mutation_data`.

subtype_resolution

The resolution of the mutation subtypes. Options are

- "none" calculates mutation frequencies across all selected grouping columns.

- "type" calculates mutation frequencies across all selected grouping columns for each variation_type separately; snv, mnv, deletion, insertion, complex, sv, ambiguous, uncategorized.
- "base_6" calculates mutation frequencies across all selected grouping columns for each variation_type with snv mutations separated by normalized_subtype; C>A, C>G, C>T, T>A, T>C, T>G. The reference context is normalized_ref.
- "base_12" calculates mutation frequencies across all selected grouping columns for each variation_type with snv mutations separated by subtype; A>C, A>G, A>T, C>A, C>G, C>T, G>A, G>C, G>T, T>A, T>C, T>G. The reference context is short_ref.
- "base_96" calculates mutation frequencies across all selected grouping columns for each variation_type with snv mutations separated by normalized_context_with_mutation, i.e. the 96-base trinucleotide context. Ex. A[C>T]A. The reference context is normalized_context.
- "base_192" calculates mutation frequencies across all selected grouping columns for each variation_type with snv mutations separated by context_with_mutation, i.e. the 192-base trinucleotide context. Ex A[G>A]A. The reference context is context.

variant_types Use this parameter to choose which variation types to include in the mutation counts. Provide a character vector of the variation types that you want to include. Alternatively, provide a character vector of the variation types that you want to exclude preceded by "-". Options are: "snv", "complex", "deletion", "insertion", "mnv", "sv", "ambiguous", "uncategorized". Ex. inclusion: "snv", exclusion: "-snv". Default includes all variants. For calculate_depth = TRUE: Regardless of whether or not a variant is included in the mutation counts, the total_depth for that position will be counted.

calculate_depth A logical variable, whether to calculate the per-group total_depth from the mutation data. If set to TRUE, the mutation data must contain a total_depth value for every sequenced base (including variants AND no-variant calls). If set to FALSE, pre-calculated per-group total_depth values may be supplied at the desired subtype_resolution using the precalc_depth_data parameter. Alternatively, if no per-group total_depth is available, per-group mutation counts will be calculated, but mutation frequency will not. In such cases, mutation subtype proportions will not be normalized to the total_depth.

precalc_depth_data A data frame or a file path to a text file containing pre-calculated per-group total_depth values. This data frame should contain the columns for the desired grouping variable(s) and the reference context at the desired subtype resolution (if applicable). The precalculated total_depth column(s) should be called one of group_depth and subtype_depth. group_depth is used for subtype resolutions of "none", "type", and all non-snv mutations in "base_6", "base_12", "base_96", and "base_192". subtype_depth is used for snv mutations in "base_6", "base_12", "base_96", and "base_192". You can access a list of context values for each subtype resolution using `MutSeqR::context_list$your_subtype_resolution`.

d_sep The delimiter used in the precalc_depth_data, if applicable. Default is tab-delimited.

summary	A logical variable, whether to return a summary table (i.e., where only relevant columns for frequencies and groupings are returned). Setting this to false returns all columns in the original mutation_data, which might make plotting more difficult, but may provide additional flexibility to power users.
retain_metadata_cols	a character vector that contains the names of the metadata columns that you would like to retain in the summary table. This may be useful for plotting your summary data. Ex. retain the "dose" column when summarising by "sample".

Value

A data frame with the mutation frequency calculated. If summary is set to TRUE, the data frame will be a summary table with the mutation frequency calculated for each group. If summary is set to FALSE, the mutation frequency will be appended to each row of the original mutation_data.

- **sum_min**: The sum of all mutations within the group, calculated using the "min" method for mutation counting. All identical mutations within a samples are assumed to be the result of clonal expansion and are thus only counted once.
- **sum_max**: The sum of all mutations within the group, calculated using the "max" method for mutaiton counting. All identical mutations within a sample are assumed to be idenpendant mutational evens and are included in the mutation frequency calculation.
- **mf_min**: The mutation frequency calculated using the "min" method for mutation counting. $mf_min = sum_min / depth$.
- **mf_max**: The mutation frequency calculated using the "max" method for mutation counting. $mf_max = sum_max / depth$.
- **proportion_min**: The proportion of each mutation subtype within the group, normalized to the depth. Calculated using the "min" method. This is only calculated if subtype_resolution is not "none". If no depth is calculated or provided, proportion is calculated without normalization to the depth.
- **proportion_max**: The proportion of each mutation subtype within the group, normalized to its read depth. Calculated using the "max" method. This is only calculated if subtype_resolution is not "none". If no depth is calculated or provided, proportion is calculated without normalization to the depth.

Examples

```
# Load example data
example_file <- system.file("extdata", "Example_files",
                           "example_mutation_data_filtered.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)

# Example 1 Calculate mutation frequency by sample.
# Calculate depth from the mutation data
mf_example <- calculate_mf(mutation_data = example_data,
                          cols_to_group = "sample")
# Example 2: Calculate the trinucleotide mutation proportions for each dose
mf_96_example <- calculate_mf(mutation_data = example_data,
                              cols_to_group = "dose",
```

[illegible]

```

677693752, 701163532))
mf_example_precalc <- calculate_mf(mutation_data = example_data,
                                   cols_to_group = "sample",
                                   calculate_depth = FALSE,
                                   precalc_depth_data = sample_depth_example)

# Example 5: Calculate MF using precalculated depth data for 6 base
# mutation subtypes per sample.
# The base_6 resolution uses reference context 'normalized_ref'; C or T.
# Our precalc_depth_data needs group_depth (depth per sample) and the
# subtype_depth (depth per sample AND per normalized_ref)
# We will create the example precalc_depth data for the base_6 resolution
# from Example 3 results for simplicity.
sample_subtype_depth_example <- mf_6_example %>%
  dplyr::select(sample, normalized_ref, group_depth, subtype_depth) %>%
  unique() %>%
  dplyr::filter(normalized_ref != "N")
mf_6_example_precalc <- calculate_mf(mutation_data = example_data,
                                   cols_to_group = "sample",
                                   subtype_resolution = "base_6",
                                   calculate_depth = FALSE,
                                   precalc_depth_data = sample_subtype_depth_example)

```

check_required_columns

Check that all required columns are present before proceeding with the function

Description

A utility function that will check that all required columns are present.

Usage

```
check_required_columns(data, required_columns)
```

Arguments

data mutation data
required_columns a list of required column names.

Value

an error

classify_variation	<i>classify_variation</i>
--------------------	---------------------------

Description

Classify the variation type of a mutation based on its ref and alt values.

Usage

```
classify_variation(ref, alt)
```

Arguments

ref	The reference allele.
alt	The alternate allele.

Value

A character indicating the type of variation.

cleveland_plot	<i>Cleveland Plot</i>
----------------	-----------------------

Description

Make a Cleveland plot for the PROAST results. Matches ToxicR.

Usage

```
cleveland_plot(results, covariate_col = NULL, output_path = NULL)
```

Arguments

results	PROAST results object.
covariate_col	Covariate column name.
output_path	Output path for the plot. If the output_path doesn't exist, it will be created. If NULL, the plots will not be exported.

Value

A list of ggplot objects for each response in results.

cluster_spectra	<i>Hierarchical Clustering</i>
-----------------	--------------------------------

Description

perform hierarchical clustering of samples based on the mutation spectra.

Usage

```
cluster_spectra(
  mf_data = mf_data,
  group_col = "sample",
  response_col = "proportion_min",
  subtype_col = "normalized_subtype",
  dist = "cosine",
  cluster_method = "ward.D"
)
```

Arguments

mf_data	A data frame containing the mutation data. This data must include a column containing the mutation subtypes, a column containing the sample/cohort names, and a column containing the response variable.
group_col	The name of the column in data that contains the sample/cohort names.
response_col	The name of the column in data that contains the response variable. Typical response variables can be the subtype mf, proportion, or count.
subtype_col	The name of the column in data that contains the mutation subtypes.
dist	the distance measure to be used. This must be one of "cosine", "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". See dist for details.
cluster_method	The agglomeration method to be used. See hclust for details.

Details

The cosine distance measure represents the inverted cosine similarity between samples:

$$\text{Cosine Dissimilarity} = 1 - \frac{\mathbf{A} \cdot \mathbf{B}}{\|\mathbf{A}\| \cdot \|\mathbf{B}\|}$$

This equation calculates the cosine dissimilarity between two vectors A and B.

Value

A dendrogram object representing the hierarchical clustering of the samples.

context_list	<i>A list of reference contexts at different resolutions</i>
--------------	--

Description

A list of reference contexts at different resolutions

Usage

context_list

Format

A list with corresponding values

denominator_dict	<i>Values used for denominators in frequency calculations</i>
------------------	---

Description

These values are used to cross reference base substitution types to their appropriate denominators for calculations. That is, "for example, the 6 base substitution frequency should be subsetting based on the normalized_ref column which would contain only T or C (i.e., the pyrimidine context for base substitutions).

Usage

denominator_dict

Format

A vector with corresponding values

f.plot.gui

*Manages plotting for PROAST***Description**

Runs through the plotting functions depending on data type and plot type.

Usage

```
f.plot.gui(
  ans.all,
  HTML = FALSE,
  model.summ = TRUE,
  display_plots = TRUE,
  results_env = NULL,
  output_type = NULL,
  filename = NULL,
  interactive_mode = TRUE,
  record_plots = FALSE
)
```

Arguments

ans.all	The proast object that gets passed to all functions.
HTML	I don't know what this does but keep it FALSE
model.summ	I don't know what this does either, but keep it TRUE
display_plots	A logical variable - whether we want to display the plots or not.
results_env	environment
output_type	The format that you wish to export the plots as.
record_plots	A logical variable indicating whether you want to record the plots and return them as a list instead of exporting them. This parameter should only be used when running the function independently or within f.plot.result. It will disrupt f.proast(), so keep the default as FALSE.

f.plot.result

*Plot the PROAST results***Description**

Independently generate the model plots from the raw results.

Usage

```
f.plot.result(
  proast_results_list,
  output_path = NULL,
  output_type = "svg",
  prefix = NULL,
  model_averaging = FALSE
)
```

Arguments

proast_results_list	The raw results list. This is the output of f.proast [1]
output_path	The file path to the output directory. If the output_path is NULL, it will save it to the working directory. If the output_path doesn't exist, it will be created.
output_type	The file type to export the plots. Options are 'svg', 'jpeg', 'pdf', 'png', 'tiff', or 'none'. If "none", the plots will be displayed to the graphics window, recorded with recordPlot(), and returned as a list.
prefix	A custom prefix to append to the file names. Default is "PROAST_".
model_averaging	A logical variable indicating whether you want to generate the model averaging figure (TRUE) or the plots of the individual models (FALSE). You plot one or the other, not both. Plotting the model averaging figure will require the function to re-run the bootstrapping so it might take a while. You may think this seems rather inefficient. Well, it is, but I'm too tired to fix it, so we all just have to deal with it for now.

Value

Generates plots. Either saves them to an output path or records them and returns them as a list.

f.proast

Run dose-response modeling using PROAST.

Description

Run dose-response modeling using PROAST.

Usage

```
f.proast(
  odt = list(),
  ans.all = 0,
  er = FALSE,
  resize = FALSE,
  scale.ans = FALSE,
```

```

const.var = FALSE,
show.warnings = FALSE,
interactive_mode = TRUE,
datatype = NULL,
model_choice = NULL,
setting_choice = NULL,
nested_model_choice = NULL,
indep_var_choice = NULL,
Vyans_input = NULL,
covariates = NULL,
custom_CES = 0.05,
model_selection = NULL,
lower_dd = NULL,
upper_dd = NULL,
selected_model = NULL,
adjust_CES_to_group_SD = NULL,
model_averaging = NULL,
num_bootstraps = NULL,
display_plots = TRUE,
add_nonzero_val_to_dat = FALSE,
nonzero_val = NULL,
detection_limit = NULL
)

```

Arguments

interactive_mode	A TRUE/FALSE value specifying whether you want to run interactively (i.e., TRUE, the default) or using command-line mode (i.e., FALSE, non-interactive). If FALSE, you must provide all other parameters.
datatype	Non-interactive mode parameter. What type of response data do you want to consider? Options are 'continuous, individual data'.
model_choice	Non-interactive mode parameter. Do you want to fit a single model or fit various nested families of models? Options are 'single model', 'select model 3 or 5 from various families of models', 'select model 3 from various nested families of models', 'select model 5 from various nested families of models', 'select model 15 in terms of RPF'. Recommended: 'select model 3 or 5 from various families of models'.
setting_choice	Non-interactive mode parameter. Do you want to fit a set of models, or choose a single model? Options are 'single model', 'set of models'. Recommended: 'set of models'.
nested_model_choice	???
indep_var_choice	Non-interactive mode parameter. The column name for the independent variable to use.
Vyans_input	Non-interactive mode parameter. The column name(s) for the response variable(s) to use. If multiple, provide as a vector.

covariates	Non-interactive mode parameter. The column name for the covariate to use. If none, enter 0.
custom_CES	Non-interactive mode parameter. The critical effect size (BMR) to use, when <code>adjust_CES_to_group_SD = 1</code> (FALSE).
model_selection	Non-interactive mode parameter. The model selection to use. Options are "Exponential model only", "Exponential and Hill model", "previous option with inverse exponential model added" (run Expon, Hill, and Inv-Expon), "previous option with lognormal DR model added" (run Expon, Hill, Inv-Expon, and LN). Recommended: "previous option with lognormal DR model added".
lower_dd	Non-interactive mode parameter. The lower constraint on d parameter. If NULL, existing defaults are used.
upper_dd	Non-interactive mode parameter. The upper constraint on d parameter. If NULL, existing defaults are used.
selected_model	Non-interactive mode parameter. Which model do you want to continue with? Options are "exponential", "Hill", "inverse exponential", "lognormal DR". The function will output results for all models regardless of this choice. Really just to bypass the menu option. Recommended: "exponential".
adjust_CES_to_group_SD	Non-interactive mode parameter. Set the BMR to the group standard deviation. Options are 1 (FALSE) or 2 (TRUE).
model_averaging	Non-interactive mode parameter. Whether to perform model averaging to calculate 90% confidence intervals. TRUE/FALSE.
num_bootstraps	Non-interactive mode parameter. The number of bootstraps to perform for model averaging. Recommended: 200.
display_plots	Non-interactive mode parameter. Whether to display plots. TRUE/FALSE.
add_nonzero_val_to_dat	Non-interactive mode parameter. When the response data contains 0s, whether to add a non-zero value to each observation. TRUE/FALSE. If TRUE, set the <code>nonzero_val</code> parameter with your desired (positive) number. If FALSE, a detection limit will be used. Provide the detection limit in the <code>detection_limit</code> parameter. If no <code>detection_limit</code> is given, the function will use the minimum non-zero value in the data. Values below the detection limit will be plotted as half the detection limit.
nonzero_val	Non-interactive mode parameter. The non-zero value to add to each observation when <code>add_nonzero_val_to_dat = TRUE</code> . Must be a positive number.
detection_limit	Non-interactive mode parameter. The detection limit to use when <code>add_nonzero_val_to_dat = FALSE</code> . If NULL, the minimum non-zero value in the data will be used. This parameter accepts a numeric value, which will be applied to all response values, or a column name in the data, which will be used to apply different detection limits to different observations.

Value

Results from PROAST.

filter_mut

Filter your mutation data

Description

This function creates a filter_mut column that will be read by the calculate_mf function. Variants with filter == TRUE will not be included in final mutation counts. This function may also remove records of given loci from the mutation data based on user specification. Running this function again on the same data will not override the previous filters. To reset previous filters, set the filter_mut column values to FALSE.

Usage

```
filter_mut(
  mutation_data,
  correct_depth = FALSE,
  correct_depth_to_indel = TRUE,
  vaf_cutoff = 1,
  snv_in_germ_mnv = FALSE,
  rm_abnormal_vaf = FALSE,
  custom_filter_col = NULL,
  custom_filter_val = NULL,
  custom_filter_rm = FALSE,
  regions = NULL,
  regions_filter,
  allow_half_overlap = FALSE,
  rg_sep = "\t",
  is_0_based_rg = TRUE,
  rm_filtered_mut_from_depth = FALSE,
  return_filtered_rows = FALSE
)
```

Arguments

- mutation_data Your mutation data.
- correct_depth A logical value. If TRUE, the function will correct the total_depth column in mutation_data in order to prevent double-counting the total_depth values for the same genomic position. For rows with the same sample contig, and start values, the total_depth will be retained for only one row. All other rows in the group will have their total_depth set to 0. The default is FALSE
- correct_depth_to_indel A logical value. If TRUE, during depth correction, should there be different total_depth values within a group of rows with the same sample, contig, and start values, the total_depth value for the row with the highest priority variation_type will be retained, while the other rows will have their total_depth set to 0. variation_type priority order is: deletion, complex,

	insertion, snv, mnv, sv, uncategorised, no_variant. If FALSE, the total_depth value for the first row in the group will be retained, while the other rows will have their total_depth set to 0. The default is TRUE.
vaf_cutoff	Filter out ostensibly germline variants using a cutoff for variant allele fraction (VAF). Any variant with a vaf larger than the cutoff will be filtered. The default is 1 (no filtering). It is recommended to use a value of 0.01 (i.e. 1%) to retain only somatic variants.
snv_in_germ_mnv	Filter out snv variants that overlap with germline mnv variants within the same samples. mnv variants will be considered germline if their vaf > vaf_cutoff. Default is FALSE.
rm_abnormal_vaf	A logical value. If TRUE, rows in mutation_data with a variant allele fraction (VAF) between 0.05 and 0.45 or between 0.55 and 0.95 will be removed. We expect variants to have a VAF ~0. 0.5, or 1, reflecting rare somatic mutations, heterozygous germline mutations, and homozygous germline mutations, respectively. Default is FALSE.
custom_filter_col	The name of the column in mutation_data to apply a custom filter to. This column will be checked for specific values, as defined by custom_filter_val. If any row in this column contains one of the specified values, that row will either be flagged in the filter_mut column or, if specified by custom_filter_rm, removed from mutation_data.
custom_filter_val	A set of values used to filter rows in mutation_data based on custom_filter_col. If a row in custom_filter_col matches any value in custom_filter_val, it will either be set to TRUE in the filter_mut column or removed, depending on custom_filter_rm.
custom_filter_rm	A logical value. If TRUE, rows in custom_filter_col that match any value in custom_filter_val will be removed from the mutation_data. If FALSE, filter_mut will be set to TRUE for those rows.
regions	Remove rows that are within or outside of specified regions. regions can be either a file path, a data frame, or a GRanges object containing the genomic ranges by which to filter. File paths will be read using the rg_sep. Users can also choose from the built-in TwinStrand's Mutagenesis Panels by inputting "Tspanel_human", "Tspanel_mouse", or "Tspanel_rat". Required columns for the regions file are "contig", "start", and "end". In a GRanges object, the required columns are "seqnames", "start", and "end".
regions_filter	Specifies how the provided regions should be applied to mutation_data. Acceptable values are "remove_within" or "keep_within". If set to "remove_within", any rows that fall within the specified regions will be removed from mutation_data. If set to "keep_within", only the rows within the specified regions will be kept in mutation_data, and all other rows will be removed.
allow_half_overlap	A logical value. If TRUE, rows that start or end in your regions, but extend outside of them in either direction will be included in the filter. If FALSE, only

```

# Apply a custom filter to flag rows with "EndRepairFillInArtifact"
# in the column 'filter'
filter_example_3 <- filter_mut(mutation_data = example_data,
                              correct_depth = TRUE,
                              vaf_cutoff = 0.01,
                              regions = "Tspanel_mouse",
                              regions_filter = "keep_within",
                              custom_filter_col = "filter",
                              custom_filter_val = "EndRepairFillInArtifact",
                              custom_filter_rm = FALSE)

# Flag snv variants that overlap with germline mnv variants.
# Subtract the alt_depth of these variants from their total_depth (treat them as N-calls).
# Return all the flagged/removed rows in a seperate data frame
filter_example_4 <- filter_mut(mutation_data = example_data,
                              correct_depth = TRUE,
                              vaf_cutoff = 0.01,
                              regions = "Tspanel_mouse",
                              regions_filter = "keep_within",
                              custom_filter_col = "filter",
                              custom_filter_val = "EndRepairFillInArtifact",
                              custom_filter_rm = FALSE,
                              snv_in_germ_mnv = TRUE,
                              rm_filtered_mut_from_depth = TRUE,
                              return_filtered_rows = TRUE)

# Flagging germline mutations...
# Found 612 germline mutations.
# Flagging SNVs overlapping with germline MNVs...
# Found 20 SNVs overlapping with germline MNVs.
# Applying custom filter...
# Flagged 2021 rows with values in <filter> column that matched EndRepairFillInArtifact
# Applying region filter...
# Removed 22 rows based on regions.
# Correcting depth...
# 909 rows had their total_depth corrected.
# Removing filtered mutations from the total_depth...
# Filtering complete.
# Returning a list: mutation_data and filtered_rows.
filtered_rows <- filter_example_4$filtered_rows
filtered_example_mutation_data <- filter_example_4$mutation_data

```

get_binom_ci

Add binomial confidence intervals to mutation frequencies.

Description

Uses the binomial distribution to create confidence intervals for mutation frequencies calculated from a single point estimate. Calculating binomial confidence intervals for mutation frequencies is not part of MutSeqR's recommended workflow, but is provided here for users who wish to use it.

Usage

```
get_binom_ci(
  mf_data,
  sum_col = "sum_min",
  depth_col = "group_depth",
  conf_level = 0.95,
  method = "wilson"
)
```

Arguments

mf_data	The data frame containing the mutation frequencies per sample. Obtained as an output from calculate_mf.
sum_col	Column name that specifies the mutation count (e.g., sum_min)
depth_col	Column name that specifies the sequencing depth (e.g., total_depth)
conf_level	Confidence interval to calculate, default 95% (0.95)
method	The method used by binom::binom.confint to calculate intervals. Default is "wilson" (recommended).

Value

A mf data frame with added columns indicating the confidence intervals.

Examples

```
example_file <- system.file("extdata", "Example_files",
                           "example_mutation_data_filtered.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)
mf <- calculate_mf(example_data)
confint <- get_binom_ci(mf_data = mf,
                       sum_col = "sum_min",
                       depth_col = "group_depth")
```

get_cpg_mutations	<i>Get mutations at CpG sites.</i>
-------------------	------------------------------------

Description

Needs to be reworked for variants >1bp. Subset the mutation data and return only mutations that are found at positions with a specific motif. The default is CpG sites, but can be customizable.

Usage

```
get_cpg_mutations(
  mutation_data,
  regions,
  variant_types = c("-no_variant"),
  motif = "CG",
  filter_mut = TRUE
)
```

Arguments

- | | |
|---------------|---|
| mutation_data | A dataframe or GRanges object containing the mutation data to be interrogated. If supplying a data frame, the genomic coordinates must be 1-based (true for mutation data imported using import_mut_data or import_vcf_data). |
| regions | A GRanges object containing the genomic regions of interest in which to look for CpG sites. Must have the metadata column "sequence" populated with the raw nucleotide sequence to search for CpGs. This object can be obtained using the get_seq.R function. |
| variant_types | Use this parameter to choose which variation_types to include in the output. Provide a character vector of the variation _types that you want to include. Options are "ambiguous", "complex", "deletion", "insertion", "mnv", "no_variant", "snv", "sv", "uncategorized". Alternatively, provide a character vector of the variation_types that you want to exclude preceded by "-". All variation_types except those excluded will be returned. Ex. inclusion: variant_types = "snv", will return only rows with variation_type == "snv". Ex. exclusion: variant_types = "-no_variant" will return all rows, except those with variation_type == "no_variant" (default). |
| motif | Default "CG", which returns CpG sites. You could in theory use an arbitrary string to look at different motifs. Use with caution. |
| filter_mut | A logical value indicating whether the function should exclude rows flagged in the filter_mut column from the output. Default is TRUE. |

Value

A GRanges object where each range is a mutation at a CpG site (a subset of mutations from the larger object provided to the function).

get_cpg_regions	<i>Get the coordinates of the CpG sites within your genomic regions</i>
-----------------	---

Description

Filters the ranges of your genomic regions to find all positions with a specific motif. The default is CpG sites, but can be customizable.

Usage

```
get_cpg_regions(regions, motif = "CG")
```

Arguments

regions	A GRanges object containing the genomic regions of interest in which to look for CpG sites. Must have the metadata column "sequence" populated with the raw nucleotide sequence to search for CpGs. This object can be obtained using the get_seq() function.
motif	Default "CG", which returns CpG sites. You could in theory use an arbitrary string to look at different motifs. Use with caution.

Value

A GRanges object where each range is a CpG site (a subset of ranges from the larger object provided to the function).

get_ref_of_mut	<i>A utility function that will return the reference context of a mutation</i>
----------------	--

Description

A utility function that will return the reference context of a mutation

Usage

```
get_ref_of_mut(mut_string)
```

Arguments

mut_string	the mutation. Ex. T>C, A[G>T]C
------------	--------------------------------

get_seq	<i>Get sequence of genomic target regions</i>
---------	---

Description

Create a GRanges object from the genomic target ranges and import raw nucleotide sequences.

Usage

```
get_seq(
  regions,
  rg_sep = "\t",
  is_0_based_rg = TRUE,
  species = NULL,
  genome = NULL,
  masked = FALSE,
  padding = 0,
  ucsc = FALSE
)
```

Arguments

<code>regions</code>	The regions metadata file to import. Can be either a file path, a data frame, or a GRanges object. File paths will be read using the <code>rg_sep</code> . Users can also choose from the built-in TwinStrand's Mutagenesis Panels by inputting "Tspanel_human", "Tspanel_mouse", or "Tspanel_rat". Required columns for the regions file are "contig", "start", and "end". In a GRanges object, the required columns are "seqnames", "start", and "end".
<code>rg_sep</code>	The delimiter for importing the regions file. The default is tab-delimited ("\t").
<code>is_0_based_rg</code>	A logical variable. Indicates whether the position coordinates in <code>regions</code> are 0 based (TRUE) or 1 based (FALSE). If TRUE, positions will be converted to 1-based (start + 1). Need not be supplied for TSpansels. Default is TRUE.
<code>species</code>	The species for which to retrieve the sequences. Species may be given as the scientific name or the common name. Ex. "Human", "Homo sapien". Used to choose the appropriate BS genome. Need not be supplied for TSpansels.
<code>genome</code>	The genome assembly version for which to retrieve the sequences. Used to choose the appropriate genome (BS genome or UCSC). Ex. hg38, hg19, mm10, mm39, rn6, rn7. Need not be supplied for TSpansels.
<code>masked</code>	A logical value indicating whether to use the masked version of the BS genome when retrieving sequences. Default is FALSE.
<code>padding</code>	An integer value by which the function will extend the range of the target sequence on both sides. Start and end coordinates will be adjusted accordingly. Default is 0.
<code>ucsc</code>	A logical value. If TRUE, the function will retrieve the sequences from the UCSC genome browser using an API. If FALSE, the function will retrieve sequences using the appropriate BSgenome package, which will be installed as needed. Default is FALSE.

Details

Consult `available.genomes(splitNameParts=FALSE, type=getOption("pkgType"))` for a full list of the available BS genomes and their associated species/genome/masked values. The BSgenome package will be installed if not already available. If using the UCSC API, the function will retrieve the sequences from the UCSC genome browser using the DAS API. See the UCSC website for available genomes: <https://genome.ucsc.edu>.

Value

a GRanges object with sequences of targeted regions.

Examples

```
# Example 1: Retrieve the sequences for TwinStrand Mouse Mutagenesis Panel
regions_seq <- get_seq(regions = "Tspanel_mouse")

# Example 2: Retrieve the sequences for custom regions
# We will load the Tspanel_human regions file as an example
# and supply it to the function as a GRanges object.
human <- load_regions_file("Tspanel_human")
regions_seq <- get_seq(regions = human,
                       is_0_based_rg = FALSE,
                       species = "human",
                       genome = "hg38",
                       masked = FALSE,
                       padding = 0)
```

import_mut_data

Import tabular mutation data

Description

Imports tabular mutation file into the local R environment.

Usage

```
import_mut_data(
  mut_file,
  mut_sep = "\t",
  is_0_based_mut = TRUE,
  sample_data = NULL,
  sd_sep = "\t",
  regions = NULL,
  custom_regions = NULL,
  rg_sep = "\t",
  is_0_based_rg = TRUE,
  padding = 0,
  genome = NULL,
  species = NULL,
  masked_BS_genome = FALSE,
  custom_column_names = NULL,
  output_granges = FALSE
)
```

Arguments

mut_file	<p>The mutation data file(s) to be imported. This can be either a data frame object or a filepath to a file or directory. If you specify a directory, the function will attempt to read all files in the directory and combine them into a single data frame. Mutation data should consist of a row for each variant. Required columns are listed below.</p> <ul style="list-style-type: none"> • contig: The name of the reference sequence. • start: The start position of the feature. • end: The half-open end position of the feature. • sample: The sample name. • ref: The reference allele at this position • alt: The left-aligned, normalized, alternate allele at this position. Multiple alt alleles called for a single position should be represented as separate rows in the table. <p>The following columns are not required, but are recommended for full package functionality:</p> <ul style="list-style-type: none"> • alt_depth: The read depth supporting the alternate allele. If not included, the function will add this column, assuming a value of 1. • total_depth: The total read depth at this position, excluding no-calls (N calls). If not present, the function will attempt to calculate the total_depth as depth - no_calls. If no_calls is not present, the function will use depth as the total_depth. • depth: The total read depth at this position, including no-calls. • no_calls: The number of no-calls (N-calls) at this position. <p>We recommend that files include a record for every sequenced position, regardless of whether a variant was called, along with the total_depth for each record. This enables site-specific depth calculations required for some downstream analyses.</p>
mut_sep	The delimiter for importing the mutation file. Default is tab-delimited.
is_0_based_mut	A logical variable. Indicates whether the position coordinates in the mutation data are 0 based (TRUE) or 1 based (FALSE). If TRUE, positions will be converted to 1-based.
sample_data	An optional file containing additional sample metadata (dose, timepoint, etc.). This can be a data frame or a file path. Metadata will be joined with the mutation data based on the sample column. Required columns are sample and any additional columns you wish to include.
sd_sep	The delimiter for importing sample data. Default is tab-delimited.
regions	An optional file containing metadata of genomic regions. Region metadata will be joined with mutation data and variants will be checked for overlap with the regions. regions can be either a file path, a data frame, or a GRanges object. File paths will be read using the rg_sep. Users can also choose from the built-in TwinStrand's Mutagenesis Panels by inputting "TSpanel_human", "TSpanel_mouse", or "TSpanel_rat". Required columns for the regions file are "contig", "start", and "end". For a GRanges object, the required columns are "seqnames", "start", and "end". Default is NULL.

rg_sep	The delimiter for importing the custom_regions. The default is tab-delimited "\t".
is_0_based_rg	A logical variable. Indicates whether the position coordinates in regions are 0 based (TRUE) or 1 based (FALSE). If TRUE, positions will be converted to 1-based (start + 1). Need not be supplied for TSpansels. Default is TRUE.
padding	An integer >= 0. Extend the range of your regions in both directions by the given amount. Ex. Structural variants and indels may start outside of the regions. Adjust the padding to include these variants in your region's ranges.
genome	The genome assembly version of the reference genome. This is required if your data does not include a context column. The function will install a BS genome for the given species/genome/masked arguments to populate the context column. Ex. Human GRCh38 = hg38 Human GRCh37 = hg19 Mouse GRCm38 = mm10 Mouse GRCm39 = mm39 Rat RGSC 6.0 = rn6 Rat mRatBN7.2 = rn7
species	The species. Required if your data does not include a context column. The function will install a BS genome for the given species/genome/masked to populate the context column. The species can be the common name of the species or the scientific name. Ex. "human" or "Homo sapiens".
masked_BS_genome	A logical value. Required when using a BS genome to populate the context column. Whether to use the masked version of the BS genome (TRUE) or not (FALSE). Default is FALSE.
custom_column_names	A list of names to specify the meaning of column headers. Since column names can vary with data, this might be necessary to digest the mutation data properly. Typical defaults are set, but can be substituted in the form of list(my_custom_contig_name = "contig", my_custom_sample_column_name = "sample"). You can change one or more of these. Set column synonyms are defined in MutSeqR::op\$column and will automatically be changed to their default value.
output_granges	A logical variable; whether you want the mutation data to output as a GRanges object. Default output (FALSE) is as a dataframe.

Value

A table where each row is a mutation, and columns indicate the location, type, and other data. If output_granges is set to TRUE, the mutation data will be returned as a GRanges object, otherwise mutation data is returned as a dataframe.

Output Column Definitions:

- short_ref: The reference base at the start position.
- normalized_ref: The short_ref in C/T-base notation for this position (e.g. A -> T, G -> C).
- context The trinucleotide context at this position. Consists of the reference base and the two flanking bases (e.g. TAC).
- normalized_context: The trinucleotide context in C/T base notation for this position (e.g. TAG -> CTA).
- variation_type The type of variant (snv, mnv, insertion, deletion, complex, sv, no_variant, ambiguous, uncategorized).

- `subtype` The substitution type for the snv variant (12-base spectrum; e.g. A>C).
- `normalized_subtype` The C/T-based substitution type for the snv variant (6-base spectrum; e.g. A>C -> T>G).
- `context_with_mutation`: The substitution type for the snv variant including the two flanking nucleotides (192-trinucleotide spectrum; e.g. T[A>C]G)
- `normalized_context_with_mutation`: The C/T-based substitution type for the snv variant including the two flanking nucleotides (96-base spectrum e.g. T[A>C]G -> C[T>G]A).
- `nchar_ref`: The length (in bp) of the reference allele.
- `nchar_alt`: The length (in bp) of the alternate allele.
- `varlen`: The length (in bp) of the variant.
- `ref_depth`: The depth of the reference allele. Calculated as `total_depth - alt_depth`, if applicable.
- `vaf` : The variant allele fraction. Calculated as `alt_depth/total_depth`.
- `gc_content`: % GC of the trinucleotide context at this position.
- `is_known`: TRUE or FALSE. Flags known variants (ID != ".").
- `row_has_duplicate`: TRUE or FALSE. Flags rows whose position is the same as that of at least one other row for the same sample.

Examples

```
# Example: Import a single mutation file. This library was sequenced with
# Duplex Sequencing using the TwinStrand Mouse Mutagenesis Panel which
# consists of 20 2.4kb targets = 48kb of sequence.
example_file <- system.file("extdata", "Example_files",
                           "example_import_mut_data.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)
# We will create an example metadata table for this data.
sample_meta <- data.frame(sample = "dna00996.1",
                          dose = "50",
                          dose_group = "High")
# Import the data
imported_example_data <- import_mut_data(mut_file = example_data,
                                         sample_data = sample_meta,
                                         regions = "Tspanel_mouse",
                                         genome = "mm10",
                                         species = "mouse",
                                         masked_BS_genome = FALSE)
```

import_vcf_data

Import a VCF file

Description

The function reads VCF file(s) and extracts the data into a dataframe.

Usage

```
import_vcf_data(
  vcf_file,
  sample_data = NULL,
  sd_sep = "\t",
  regions = NULL,
  rg_sep = "\t",
  is_0_based_rg = FALSE,
  padding = 0,
  genome = NULL,
  species = NULL,
  masked_BS_genome = FALSE,
  output_granges = FALSE
)
```

Arguments

vcf_file The path to the .vcf (.gvcf, gzip, bgzip) to be imported. If you specify a directory, the function will attempt to read all files in the directory and combine them into a single table. VCF files should follow the VCF specifications, version 4.5. Multisample VCF files are not supported; VCF files must contain one sample each. Required fields are listed below.

- **FIXED FIELDS**
- **CHROM:** The name of the reference sequence. Equivalent to `contig`.
- **POS:** The 1-based start position of the feature. Equivalent to `start`.
- **REF:** The reference allele at this position.
- **ALT:** The left-aligned, normalized, alternate allele at this position. Multiple alt alleles called for a single position should be represented as separate rows in the table.
- **INFO FIELDS**
- **END:** The half-open end position of the feature.
- **sample:** An identifying field for your samples; either in the INFO field or as the header to the FORMAT field.

The following FORMAT fields are not required, but are recommended for full package functionality:

- **AD:** The allelic depths for the reference and alternate allele in the order listed. The sum of AD is equivalent to the `total_depth` (read depth at this position excluding N-calls).
- **DP:** The read depth at this position (including N-calls). Equivalent to `depth`. Note that in many VCF files, the DP field is defined as `total_depth`. However, in most cases, the DP field includes N-calls.
- **VD:** The read depth supporting the alternate allele. If not included, the function will add this column, assuming a value of 1. Equivalent to `alt_depth`.

We recommend that files include a record for every sequenced position, regardless of whether a variant was called, along with the AD for each record. This enables site-specific depth calculations required for some downstream analyses.

	AD is used to calculate the <code>total_depth</code> (the read depth excluding No-calls). If AD is not available, the DP field will be used as the <code>total_depth</code> .
<code>sample_data</code>	An optional file containing additional sample metadata (dose, timepoint, etc.). This can be a data frame or a file path. Metadata will be joined with the mutation data based on the sample column. Required columns are sample and any additional columns you wish to include.
<code>sd_sep</code>	The delimiter for importing sample metadata tables. Default is tab-delimited.
<code>regions</code>	An optional file containing metadata of genomic regions. Region metadata will be joined with mutation data and variants will be checked for overlap with the regions. <code>regions</code> can be either a file path, a data frame, or a GRanges object. File paths will be read using the <code>rg_sep</code> . Users can also choose from the built-in TwinStrand's Mutagenesis Panels by inputting "Tspanel_human", "Tspanel_mouse", or "Tspanel_rat". Required columns for the regions file are "contig", "start", and "end". For a GRanges object, the required columns are "seqnames", "start", and "end". Default is NULL.
<code>rg_sep</code>	The delimiter for importing the custom_regions. The default is tab-delimited "\t".
<code>is_0_based_rg</code>	A logical variable. Indicates whether the position coordinates in regions are 0 based (TRUE) or 1 based (FALSE). If TRUE, positions will be converted to 1-based (start + 1). Need not be supplied for TSpansels. Default is TRUE.
<code>padding</code>	Extend the range of your regions in both directions by the given amount. Ex. Structural variants and indels may start outside of the regions. Adjust the padding to include these variants in your region's ranges.
<code>genome</code>	The genome assembly version of the reference genome. This is required if your data does not include a context column. The function will install a BS genome for the given species/genome/masked arguments to populate the context column. Ex. Human GRCh38 = hg38 Human GRCh37 = hg19 Mouse GRCm38 = mm10 Mouse GRCm39 = mm39 Rat RGSC 6.0 = rn6 Rat mRatBN7.2 = rn7
<code>species</code>	The species. Required if your data does not include a context column. The function will install a BS genome for the given species/genome/masked to populate the context column. The species can be the common name of the species or the scientific name. Ex. "human" or "Homo sapiens".
<code>masked_BS_genome</code>	A logical value. Required when using a BS genome to poulate the context column. Whether to use the masked version of the BS genome (TRUE) or not (FALSE). Default is FALSE.
<code>output_granges</code>	TRUE or FALSE; whether you want the mutation data to output as a GRanges object. Default output is as a dataframe.

Value

A table where each row is a mutation, and columns indicate the location, type, and other data. If `output_granges` is set to TRUE, the mutation data will be returned as a GRanges object, otherwise mutation data is returned as a dataframe.

Output Column Definitions:

- ## Examples

[illegible]

install_ref_genome	<i>Install the reference genome for the specified organism.</i>
--------------------	---

Description

This function will use BSgenome to install the reference genome for a specified organism and assembly version.

Usage

```
install_ref_genome(organism, genome, masked = FALSE)
```

Arguments

organism	the name of the organism for which to install the reference genome. This can be the scientific name or a common name. For example Homo Sapiens, H. sapiens, or human
genome	The reference genome assembly version. Ex. hg18, mm10, rn6.
masked	Logical value. Whether to search for the 'masked' BSgenome. Default is FALSE.

Value

a BSgenome object

load_regions_file	<i>Imports the regions file</i>
-------------------	---------------------------------

Description

A helper function to import the regions metadata file and return a GRanges object.

Usage

```
load_regions_file(regions, rg_sep = "\t", is_0_based_rg = TRUE)
```

Arguments

regions	The regions metadata file to import. Can be either a file path, a data frame, or a GRanges object. File paths will be read using the rg_sep. Users can also choose from the built-in TwinStrand's Mutagenesis Panels by inputting "Tspanel_human", "Tspanel_mouse", or "Tspanel_rat". Required columns for the regions file are "contig", "start", and "end". In a GRanges object, the required columns are "seqnames", "start", and "end".
---------	---

rg_sep	The delimiter for importing the custom_regions. The default is tab-delimited "\t".
is_0_based_rg	A logical variable. Indicates whether the position coordinates in regions are 0 based (TRUE) or 1 based (FALSE). If TRUE, positions will be converted to 1-based (start + 1). Need not be supplied for TSpansels. Default is TRUE.

Value

a GRanges object of the imported regions metadata file.

lollipop_mutations	<i>Plot mutations in lollipop plot</i>
--------------------	--

Description

TO DO: Create plt without trackViewer package. Uses the trackViewer package to plot mutations in a lollipop plot in specific regions as defined by the user input.

Usage

```
lollipop_mutations(species = "human", mutations, ...)
```

Arguments

species	One of "human" or "mouse"
mutations	A GRanges object with mutation data
...	Additional arguments to trackViewer::lollipop (e.g., ranges = GRanges("chr1", IRanges(104, 109))) Suggests trackViewer lollipop

model_mf	<i>Perform linear modelling on mutation frequency for given fixed and random effects</i>
----------	--

Description

model_mf will fit a linear model to analyse the effect(s) of given factor(s) on mutation frequency and perform specified pairwise comparisons. This function will fit either a generalized linear model ([glm](#)) or, if supplied random effects, a generalized linear mixed-effects model ([glmer](#)). Pairwise comparisons are conducted using the doBy library ([esticon](#)) and estimates are then back-transformed. The delta method is employed to approximate the back-transformed standard-errors. A Sidak correction is applied to adjust p-values for multiple comparisons.

Usage

```

model_mf(
  mf_data,
  fixed_effects,
  test_interaction = TRUE,
  random_effects = NULL,
  reference_level,
  muts = "sum_min",
  total_count = "group_depth",
  contrasts = NULL,
  cont_sep = "\t",
  ...
)

```

Arguments

<code>mf_data</code>	The data frame containing the mutation frequency data. Mutation counts and total sequencing depth should be summarized per sample alongside columns for your fixed effects. This data can be obtained using <code>calculate_mf(summary=TRUE)</code> .
<code>fixed_effects</code>	The name(s) of the column(s) that will act as the fixed_effects (factor/independent variable) for modelling mutation frequency.
<code>test_interaction</code>	a logical value. Whether or not your model should include the interaction between the fixed_effects.
<code>random_effects</code>	The name of the column(s) to be analysed as a random effect in the model. Providing this effect will cause the function to fit a generalized linear mixed-effects model.
<code>reference_level</code>	Refers to one of the levels within each of your fixed_effects. The coefficient for the reference level will represent the baseline effect. The coefficients of the other levels will be interpreted in relation to the reference_level as deviations from the baseline effect.
<code>muts</code>	The column containing the mutation count per sample.
<code>total_count</code>	The column containing the sequencing depth per sample.
<code>contrasts</code>	a data frame or a filepath to a file that will provide the information necessary to make pairwise comparisons between groups. The table must consist of two columns. The first column will be a group within your fixed_effects and the second column must be the group that it will be compared to. The values must correspond to entries in your mf_data column for each fixed effect. Put the group that you expect to have the higher mutation frequency in the 1st column and the group that you expect to have a lower mutation frequency in the second column. For multiple fixed effects, separate the levels of each fixed_effect of a group with a colon. Ensure that all fixed_effects are represented in each entry for the table. See details for examples.
<code>cont_sep</code>	The delimiter for importing the contrast table file. Default is tab-delimited.
<code>...</code>	Extra arguments for <code>glm</code> or <code>glmer</code> . The <code>glmer</code> function is used when a random_effect is supplied, otherwise, the model uses the <code>glm</code> function.

Details

`fixed_effects` are variables that have a direct and constant effect on the dependent variable (ie mutation frequency). They are typically the experimental factors or covariates of interest for their impact on the dependent variable. One or more `fixed_effect` may be provided. If you are providing more than one fixed effect, avoid using correlated variables; each fixed effect must independently predict the dependent variable. Ex. `fixed_effects = c("dose", "genomic_target", "tissue", "age", etc)`.

Interaction terms enable you to examine whether the relationship between the dependent and independent variable changes based on the value of another independent variable. In other words, if an interaction is significant, then the relationship between the fixed effects is not constant across all levels of each variable. Ex. Consider investigating the effect of dose group and tissue on mutation frequency. An interaction between dose and tissue would capture whether the dose response differs between tissues.

`random_effects` account for the unmeasured sources of statistical variance that affect certain groups in the data. They help account for unobserved heterogeneity or correlation within groups. Ex. If your model uses repeated measures within a sample, `random_effects = "sample"`.

Setting a `reference_level` for your fixed effects enhances the interpretability of the model. Ex. Consider a `fixed_effect` "dose" with levels 0, 25, 50, and 100 mg/kg. Intuitively, the `reference_level` would refer to the negative control dose, "0" since we are interested in testing how the treatment might change mutation frequency relative to the control.

Examples of contrasts:

If you have a `fixed_effect` "dose" with dose groups 0, 25, 50, 100, then the first column would contain the treated groups (25, 50, 100), while the second column would be 0, thus comparing each treated group to the control group.

25 0

50 0

100 0

Alternatively, if you would like to compare mutation frequency between treated dose groups, then the contrast table would look as follows, with the lower dose always in the second column, as we expect it to have a lower mutation frequency. Keeping this format aids in interpretability of the estimates for the pairwise comparisons. Should the columns be reversed, with the higher group in the second column, then the model will compute the fold-decrease instead of the fold-increase.

100 25

100 50

50 25

Ex. Consider the scenario where the `fixed_effects` are "dose" (0, 25, 50, 100) and "genomic_target" ("chr1", "chr2"). To compare the three treated dose groups to the control for each genomic target, the contrast table would look like:

25:chr1 0:chr1

50:chr1 0:chr1

100:chr1 0:chr1

25:chr2 0:chr2

50:chr2 0:chr2

100:chr2 0:chr2

Troubleshooting: If you are having issues with convergence for your generalized linear mixed-effects model, it may be advisable to increase the tolerance level for convergence checking during model fitting. This is done through the `control` argument for the `lme4::glmer` function. The default tolerance is `tol = 0.002`. Add this argument as an extra argument in the `model_mf` function. Ex. `control = lme4::glmerControl(check.conv.grad = lme4::.makeCC("warning", tol = 3e-3, relTol = NULL))`

Value

Model results are output as a list. Included are:

- `model_data`: the supplied `mf_data` with added column for the Pearson's residuals of the model.
- `summary`: the summary of the model.
- `anova`: the analysis of variance for models with two or more effects. [Anova\(model\)](#)
- `residuals_histogram`: the Pearson's residuals plotted as a histogram. This is used to check whether the variance is normally distributed. A symmetric bell-shaped histogram, evenly distributed around zero indicates that the normality assumption is likely to be true.
- `residuals_qq_plot`: the Pearson's residuals plotted in a quantile-quantile plot. For a normal distribution, we expect points to roughly follow the $y=x$ line.
- `point_estimates_matrix`: the contrast matrix used to generate point-estimates for the fixed effects.
- `point_estimates`: the point estimates for the fixed effects.
- `pairwise_comparisons_matrix`: the contrast matrix used to conduct the pairwise comparisons specified in the contrasts.
- `pairwise_comparisons`: the results of pairwise comparisons specified in the contrasts.

Examples

```
# Example 1: Model MFmin by dose
example_file <- system.file("extdata", "Example_files",
                           "example_mutation_data_filtered.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)
mf_example <- calculate_mf(mutation_data = example_data,
                          cols_to_group = "sample",
                          retain_metadata_cols = "dose")
# Create a contrasts table to define pairwise comparisons
# We will compare all treated groups to the control group
contrasts <- data.frame(col1 = c("12.5", "25", "50"),
                        col2 = c("0", "0", "0"))

# Fit the model
model1 <- model_mf(mf_data = mf_example,
                  fixed_effects = "dose",
                  reference_level = "0",
                  muts = "sum_min",
                  total_count = "group_depth",
```

```

        contrasts = contrasts)
# The residuals histogram and QQ plot will help you assess the normality
# of the residuals.
model1$summary # Model Summary
model1$point_estimates # Point Estimates: Mean MFmin by dose
model1$pairwise_comparisons # Pairwise Comparisons
# All treated doses exhibited a significant increase in mutation frequency
# compared to the control.

# Plot the results using plot_model_mf()
plot <- plot_model_mf(model1,
  plot_type = "bar",
  x_effect = "dose",
  plot_error_bars = TRUE,
  plot_signif = TRUE,
  x_order = c("0", "12.5", "25", "50"),
  x_label = "Dose (mg/kg-bw/d)",
  y_label = "Estimated Mean MF (mutations/bp)",
  plot_title = "")

# Example 2: Model MFmin by dose and genomic target
# We will compare the treated groups to the control group for each genomic
# target

# Calculate MF
mf_example2 <- calculate_mf(mutation_data = example_data,
  cols_to_group = c("sample", "label"),
  retain_metadata_cols = "dose")

# Create a contrasts table to define pairwise comparisons

  reference_level = c("0", "chr1"),
  muts = "sum_min",
  total_count = "group_depth",
  contrasts = contrasts2,
  control = lme4::glmerControl(optimizer = "bobyqa",
    optCtrl = list(maxfun = 2e5)))

model2$summary # Fits a GLMM
model2$point_estimates
model2$pairwise_comparisons

# Plot the results using plot_model_mf()

```

```

# Define the order of the labels for the x-axis
label_order <- model2$point_estimates %>%
  dplyr::filter(dose == "50") %>%
  dplyr::arrange(Estimate) %>%
  dplyr::pull(label)
# Define the order of the doses for the fill
dose_order <- c("0", "12.5", "25", "50")
plot <- plot_model_mf(model = model2,
  plot_type = "bar",
  x_effect = "label",
  plot_error_bars = TRUE,
  plot_signif = TRUE,
  ref_effect = "dose",
  x_order = label_order,
  fill_order = dose_order,
  x_label = "Target",
  y_label = "MF (mutations/bp)",
  fill_label = "Dose",
  plot_title = "",
  custom_palette = c("#ef476f",
    "#ffd166",
    "#06d6a0",
    "#118ab2"))
# The output is a ggplot object and can be modified using ggplot2
# functions. For example, to rotate the x-axis labels by 90 degrees,
# use the following code:
p <- plot + ggplot2::theme(axis.text.x = ggplot2::element_text(angle = 90))

```

op

Column names for mut tables

Description

A list of column specifications

Usage

op

Format

A list with potential variable column names

plot_bubbles

*Generate Bubble Plots***Description**

Produces a ggplot object of bubble plots from given mutation data. Optionally, bubble plots can be faceted and coloured by a specified column.

Usage

```
plot_bubbles(
  mutation_data,
  size_by = "alt_depth",
  facet_col = NULL,
  color_by = "normalized_subtype",
  circle_spacing = 1,
  circle_outline = "none",
  circle_resolution = 50,
  custom_palette = NULL
)
```

Arguments

mutation_data	Data frame containing the mutation data.
size_by	The column name by which to size the circles. Recommended values are "alt_depth" or "vaf".
facet_col	The column name by which to facet . If NULL, no facetting will be done. Default is NULL.
color_by	The column name by which to colour the mutations. Default is "normalized_subtype".
circle_spacing	Numerical value to adjust the spacing between circles. Default is 1.
circle_outline	Colour for the circle outline. Default is "none", resulting in no outline colour. Other accepted values are colours in the R language.
circle_resolution	Number of points to use for the circle resolution. Default is 50.
custom_palette	A named vector of colors to be used for the mutation subtypes. The names of the vector should correspond to the levels in color_by. Alternatively, you can specify a color palette from the RColorBrewer package. See brewer.pal for palette options. You may visualize the palettes at the ColorBrewer website: https://colorbrewer2.org/ . Default is NULL.

Details

The function will plot a circle for each mutation in mutation_data. Mutations flagged by the filter_mut column will be excluded from the plot. The size of the circle is determined by the size_by parameter. Sizing by the "alt_depth" or the "vaf" will give users the ability to visualize the the distribution of recurrent mutations within their data with large multiplets having a large circle.

Value

A ggplot object with the bubble plot, faceted if specified.

Examples

```
example_file <- system.file("extdata", "Example_files",
                             "example_mutation_data_filtered.rds",
                             package = "MutSeqR")
example_data <- readRDS(example_file)
plot <- plot_bubbles(mutation_data = example_data,
                     facet_col = "dose_group")
```

plot_ci

*plot_ci***Description**

Plot confidence intervals

Usage

```
plot_ci(
  data,
  order = "none",
  custom_order = NULL,
  nudge = 0.3,
  log_scale = FALSE,
  x_lab = NULL,
  y_lab = NULL,
  title = NULL
)
```

Arguments

data	A data frame with the results of the BMD analysis. Data must contain columns "Response", "BMD", "BMDL", and "BMDU". BMD values can be NA.
order	Indicates how the responses should be ordered. Options are "none" (default), "asc" for ascending BMD values, "desc" for descending BMD values, or a custom order.
custom_order	A character vector with the custom order of the Responses.
nudge	A numeric value to nudge the text labels away from points. Default is 0.3.
log_scale	A logical value indicating if the x-axis should be in log10 scale. Default is false.
x_lab	A character string with the x-axis label. Default is "BMD" or "log10(BMD)" if log_scale is TRUE.
y_lab	A character string with the y-axis label. Default is "Response".
title	A character string with the plot title. Default is "BMD with 90% Confidence Intervals".

Value

a ggplot object

Examples

```
# Plot results from PROAST and ToxicR
dat <- data.frame(Response = c("PROAST MF Min", "PROAST MF Max", "ToxicR MF Min", "ToxicR MF Max"),
                  BMD = c(NA, NA, 9.641894, 8.100164),
                  BMDL = c(7.38, 2.98, 8.032936, 5.463013),
                  BMDU = c(10.9, 7.68, 10.97636, 10.04638))
plot <- plot_ci(dat)
```

plot_mean_mf

Plot the Mean Mutatation Frequency

Description

This function calculates the mean mutation frequency across samples for given groups and plots the results.

Usage

```
plot_mean_mf(
  mf_data,
  group_col = "dose",
  fill_col = NULL,
  mf_type = "both",
  plot_type = "line",
  plot_errorBars = TRUE,
  plot_indiv_vals = TRUE,
  group_order = "none",
  group_order_input = NULL,
  add_labels = "mean_count",
  scale_y_axis = "linear",
  x_lab = NULL,
  y_lab = NULL,
  plot_title = NULL,
  custom_palette = NULL,
  plot_legend = TRUE
)
```

Arguments

mf_data A data frame containing the mutation frequency data. This is obtained from the calculate_mf function with SUMMARY = TRUE.

group_col	The column(s) in mf_data by which to calculate the mean. When supplying more than one column, the values of all group columns will be concatenated into a single value by which to calculate the mean. Values will be displayed along the x-axis. Ex. "dose" or c("dose", "tissue").
fill_col	An optional column name in the data used to define the fill aesthetic in the plot. If fill_col has multiple levels within each group_col level, the mean will be calculated for each level of fill_col (recommend plot_type = "line" for this use case). Default is NULL.
mf_type	The type of mutation frequency to plot. Options are "min", "max", "both", or "stacked". If "both", the min and max mutation frequencies are plotted side by side. "stacked" can be chosen for bar plot_type only. If "stacked", the difference between the min and max MF is stacked on top of the min MF such that the total height of both bars represent the max MF. Default is "min".
plot_type	The type of plot to create. Options are "bar" or "line". Default is "bar".
plot_errorBars	Whether to plot the error bars. Default is TRUE. Error bars are standard error of the mean.
plot_indiv_vals	Whether to plot the individual values as data points. Default is FALSE.
group_order	The order of the groups along the x-axis. ' Options include: <ul style="list-style-type: none"> • none: No ordering is performed. Default. • smart: Groups are ordered based on the sample names. • arranged: Groups are ordered based on one or more factor column(s) in mf_data. Factor column names are passed to the function using the group_order_input. • custom: Groups are ordered based on a custom vector of group names. The custom vector is passed to the function using the group_order_input.
group_order_input	The order of the groups if group_order is "custom". The column name by which to arrange groups if group_order is "arranged". If "custom", and using more than one group_col, values are concatenated in the order listed, separated by a "_".
add_labels	The data labels to display on the plot. Either "indiv_count", "indiv_MF", "mean_count", "mean_MF", or "none". Count labels display the number of mutations, MF labels display the mutation frequency. Mean plots the mean value. Indiv plots the labels for individual data points (only if plot_indiv_vals = TRUE). Default is "none".
scale_y_axis	The scale of the y axis. Either "linear" or "log". Default is "linear".
x_lab	The x-axis label. Default is the value of group_col.
y_lab	The y-axis label. Default is "Mutation Frequency (mutations/bp)".
plot_title	The title of the plot. Default is "Mean Mutation Frequency".
custom_palette	A custom color palette to use for the plot. Input a character vector of colours. Input a named character vector to specify colours to specific groups. Fill labels will be constructed by the following components

1. "Mean/Individual" if plot_indiv_vals = TRUE, fill labels will specify Mean/Individual values.
 2. "min/max" if mf_type = "both" or "stacked", fill labels will specify min/max values.
 3. fill_col value. Name colours to match the fill labels. Default is NULL. If no custom_palette, a rainbow palette is generated. Min/Max values and Mean/Individual values will be the same colour, different shades.
- plot_legend Logical. Whether to show the fill (and color) legend. Default is TRUE.

Value

a ggplot object

Examples

```
example_file <- system.file("extdata", "Example_files",
                           "example_mutation_data_filtered.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)
example_data$dose_group <- factor(example_data$dose_group,
                                levels = c("Control", "Low",
                                           "Medium", "High"))

mf <- calculate_mf(mutation_data = example_data,
                  cols_to_group = "sample",
                  subtype_resolution = "none",
                  retain_metadata_cols = "dose_group")

plot <- plot_mean_mf(mf_data = mf,
                    group_col = "dose_group",
                    mf_type = "min",
                    plot_type = "line",
                    fill_col = "dose_group",
                    plot_errorBars = TRUE,
                    plot_indiv_vals = TRUE,
                    add_labels = "none")
```

plot_mf

Plot the Mutation Frequency

Description

This function creates a plot of the mutation frequency.

Usage

```
plot_mf(
  mf_data,
  group_col,
  plot_type = "bar",
```

```

mf_type = "min",
fill_col = NULL,
custom_palette = NULL,
group_order = "none",
group_order_input = NULL,
labels = "count",
scale_y_axis = "linear",
x_lab = NULL,
y_lab = NULL,
title = NULL
)

```

Arguments

mf_data	A data frame containing the mutation frequency data. This is obtained from the calculate_mf function with SUMMARY = TRUE.
group_col	The name of the column containing the sample/group names for the x-axis.
plot_type	The type of plot to create. Options are "bar" or "point".
mf_type	The type of mutation frequency to plot. Options are "min", "max", "both", or "stacked". If "both", the min and max mutation frequencies are plotted side by side. "stacked" can be chosen for bar plot_type only. If "stacked", the difference between the min and max MF is stacked on top of the min MF such that the total height of both bars represent the max MF.
fill_col	The name of the column containing the fill variable.
custom_palette	A character vector of colour codes to use for the plot. If NULL, a default palette is used
group_order	The order of the samples/groups along the x-axis. ' Options include: <ul style="list-style-type: none"> • none: No ordering is performed. Default. • smart: Samples are ordered based on the sample names. • arranged: Samples are ordered based on one or more factor column(s) in mf_data. Factor column names are passed to the function using the group_order_input. • custom: Samples are ordered based on a custom vector of sample names. The custom vector is passed to the function using the group_order_input.
group_order_input	The order of the samples/groups if group_order is "custom". The column name by which to arrange samples/groups if group_order is "arranged"
labels	The data labels to display on the plot. Either "count", "MF", or "none". Count labels display the number of mutations, MF labels display the mutation frequency.
scale_y_axis	The scale of the y axis. Either "linear" or "log".
x_lab	The label for the x axis.
y_lab	The label for the y axis.
title	The title of the plot.

Value

A ggplot object

Examples

```
example_file <- system.file("extdata", "Example_files",
                             "example_mutation_data_filtered.rds",
                             package = "MutSeqR")
example_data <- readRDS(example_file)
example_data$dose_group <- factor(example_data$dose_group,
                                  levels = c("Control", "Low",
                                              "Medium", "High"))

mf <- calculate_mf(mutation_data = example_data,
                  cols_to_group = "sample",
                  subtype_resolution = "none",
                  retain_metadata_cols = "dose_group")

plot <- plot_mf(mf_data = mf,
               group_col = "sample",
               plot_type = "bar",
               mf_type = "min",
               fill_col = "dose_group",
               group_order = "arranged",
               group_order_input = "dose_group",
               labels = "count",
               title = "Mutation Frequency per Sample")
```

plot_model_mf

Plot your mf model

Description

Provide a visualization of the point estimates derived using model_mf()

Usage

```
plot_model_mf(
  model,
  plot_type = "point",
  x_effect = NULL,
  plot_errorBars = TRUE,
  plot_signif = TRUE,
  ref_effect = NULL,
  x_order = NULL,
  fill_order = NULL,
  x_label = NULL,
  y_label = NULL,
  plot_title = NULL,
  fill_label = NULL,
  custom_palette = NULL
)
```

Arguments

model	A model object created using model_mf()
plot_type	The type of plot to create. Options are "bar" or "point".
x_effect	If there are multiple fixed effects in the model, specify the fixed effect to plot on the x-axis. The other will be used in the fill aesthetic. Currently, only 2 fixed effects are supported.
plot_errorBars	Logical. If TRUE, the estimated standard error will be added to the plot.
plot_signif	Logical. If TRUE, will add significance labels based on the pairwise_comparisons data frame in the model object. This is only valid if you supplied a contrasts table to model_mf(). Symbols will be applied to plotted values that are significantly different from the reference. Your contrasts table is structured as a data frame with two columns, each containing levels of the fixed effects to be contrasted. When adding significance labels, symbols will be added to the values defined in the first column, while the second column will represent the reference. A different symbol will be used for each unique reference level. If a single plotted value has been contrasted against multiple references, then it will gain multiple symbols for each significance difference.
ref_effect	The fixed effect to use as the reference level when adding significance labels. Only applicable if using two fixed effects.
x_order	A character vector indicating the order of the levels for the x_effect.
fill_order	A character vector indicating the order of the levels for the fill aesthetic, if applicable.
x_label	The label for the x-axis.
y_label	The label for the y-axis.
plot_title	The title of the plot.
fill_label	The label for the fill aesthetic, if applicable.
custom_palette	A vector of colors to use for the fill and color aesthetics. If not provided, a default palette will be used. When plotting a model that has a single fixed effect, you can specify colors for "fill" and "color" using a named vector. Likewise, when plotting a model with two fixed effects, you can specify colors for the levels within your fill variable.

Details

See model_mf() for examples.

Value

A ggplot object.

plot_radar

Create a radar plot

Description

Create a radar plot

Usage

```
plot_radar(mf_data, response_col, label_col, facet_col, indiv_y = TRUE)
```

Arguments

mf_data	A data frame with the data to plot
response_col	The column with the response values
label_col	The column with the labels for the radar plot.
facet_col	The column with the group to facet the radar plots.
indiv_y	A logical indicating whether to use individual y-axis scales for each plot.

Value

A radar plot

Examples

```
# Plot the mean MFmin of each genomic target per dose group
# Order the genomic targets by their genic context.
# Load the example data and calculate MF
example_file <- system.file("extdata",
                             "example_mutation_data_filtered.rds",
                             package = "MutSeqR")
example_data <- readRDS(example_file)
mf <- calculate_mf(mutation_data = example_data,
                  cols_to_group = c("sample", "label"),
                  retain_metadata_cols = c("dose_group", "genic_context"))
# Define the order of the genomic targets
label_order <- mf %>% dplyr::arrange(genic_context) %>%
  pull(label) %>%
  unique()
# Calculate the mean MF per dose_group for each target.
mean <- mf %>%
  dplyr::group_by(dose_group, label) %>%
  dplyr::summarise(mean = mean(mf_min))
# Set the order of each column
mean$dose_group <- factor(mean$dose_group,
                          levels = c("Control",
                                       "Low",
                                       "Medium"),
```

```

                                "High"))
mean$label <- factor(mean$label,
                     levels = label_order)
# Plot
plot <- plot_radar(mf_data = mean,
                  response_col = "mean",
                  label_col = "label",
                  facet_col = "dose_group",
                  indiv_y = FALSE)

```

plot_spectra

Transition-transversion plot

Description

Given mf data, construct a plot displaying the mutation subtypes observed in a cohort.

Usage

```

plot_spectra(
  mf_data,
  group_col = "sample",
  subtype_resolution = "base_6",
  response = "proportion",
  mf_type = "min",
  group_order = "none",
  group_order_input = NULL,
  dist = "cosine",
  cluster_method = "ward.D",
  custom_palette = NULL,
  x_lab = NULL,
  y_lab = NULL
)

```

Arguments

mf_data	A data frame containing the mutation frequency data at the desired subtype resolution. This is obtained using the 'calculate_mf' function with subtype_resolution set to the desired resolution. Data must include a column containing the group_col, a column containing the mutation subtypes, a column containing the desired response variable (mf, proportion, sum) for the desired mf_type (min or max), and if applicable, a column containing the variable by which to order the samples/groups.
group_col	The name of the column(s) in the mf data that contains the sample/group names. This will generally be the same values used for the cols_to_group argument in the calculate_mf function. However, you may also use groups that are at a higher level of the aggregation in mf_data.

subtype_resolution	The subtype resolution of the mf data. Options are base_6, base_12, base_96, base_192, or type. Default is base_6.
response	The desired response variable to be plotted. Options are mf, proportion, or sum. Default is proportion. Your mf_data must contain columns with the name of your desired response: mf_min, mf_max, proportion_min, proportion_max, sum_min, and sum_max.
mf_type	The mutation counting method to use. Options are min or max. Default is min.
group_order	The method for ordering the samples within the plot. Options include: <ul style="list-style-type: none"> • none: No ordering is performed. Default. • smart: Groups are automatically ordered based on the group names (alphabetical, numerical) • arranged: Groups are ordered based on one or more factor column(s) in mf_data. Column names are passed to the function using the group_order_input. • custom: Groups are ordered based on a custom vector of group names. The custom vector is passed to the function using the group_order_input. • clustered: Groups are ordered based on hierarchical clustering. The dissimilarity matrix can be specified using the dist argument. The agglomeration method can be specified using the cluster_method argument.
group_order_input	A character vector specifying details for the group order method. If group_order is arranged, group_order_input should contain the column name(s) to be used for ordering the samples. If group_order is custom, group_order_input should contain the custom vector of group names.
dist	The dissimilarity matrix for hierarchical clustering. Options are cosine, euclidean, maximum, manhattan, canberra, binary or minkowski. The default is cosine. See dist for details.
cluster_method	The agglomeration method for hierarchical clustering. Options are ward.D, ward.D2, single, complete, average (= UPGMA), mcquitty (= WPGMA), median (= WPGMC) or centroid (= UPGMC). The default is Ward.D. See hclust for details.
custom_palette	A named vector of colors to be used for the mutation subtypes. The names of the vector should correspond to the mutation subtypes in the data. Alternatively, you can specify a color palette from the RColorBrewer package. See brewer.pal for palette options. You may visualize the palettes at the ColorBrewer website: https://colorbrewer2.org/ . Default is NULL.
x_lab	The label for the x-axis. Default is the value of group_col.
y_lab	The label for the y-axis. Default is the value of response_col.

Examples

```
# Load example data
example_file <- system.file("extdata", "Example_files",
                           "example_mutation_data_filtered.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)
```

```

# Example 1: plot the proportion of 6-based mutation subtypes
# for each sample, organized by dose group:

# Calculate the mutation frequency data at the 6-base resolution.
# Retain the dose_group column to use for ordering the samples.
mf_data <- calculate_mf(mutation_data = example_data,
                        cols_to_group = "sample",
                        subtype_resolution = "base_6",
                        retain_metadata_cols = "dose_group")
# Set the desired order for the dose_group levels.
mf_data$dose_group <- factor(mf_data$dose_group,
                             levels = c("Control", "Low", "Medium", "High"))

# Plot the mutation spectra
plot <- plot_spectra(mf_data = mf_data,
                     group_col = "sample",
                     subtype_resolution = "base_6",
                     response = "proportion",
                     group_order = "arranged",
                     group_order_input = "dose_group")

# Example 2: plot the proportion of 6-based mutation subtypes
# for each sample, ordered by hierarchical clustering:
plot <- plot_spectra(mf_data = mf_data,
                     group_col = "sample",
                     subtype_resolution = "base_6",
                     response = "proportion",
                     group_order = "clustered")

```

plot_trinucleotide	<i>Plot the trinucleotide spectrum</i>
--------------------	--

Description

Creates barplots of the trinucleotide spectrum for all levels of a given group.

Usage

```

plot_trinucleotide(
  mf_96,
  response = "proportion",
  mf_type = "min",
  group_col = "dose",
  indiv_y = FALSE,
  sum_totals = TRUE,
  output_path = NULL,
  output_type = "svg"
)

```

Arguments

mf_96	A data frame containing the mutation frequency data at the 96-base resolution. This should be obtained using the 'calculate_mf' with subtype_resolution set to 'base_96'. Generally, cols_to_group should be the same as 'group_col'.
response	A character string specifying the type of response to plot. Must be one of 'frequency', 'proportion', or 'sum'.
mf_type	A character string specifying the mutation count method to plot. Must be one of 'min' or 'max'. Default is 'min'.
group_col	A character string specifying the column(s) in 'mf_96' to group the data by. Default is 'sample'. The sum, proportion, or frequency will be plotted for all unique levels of this group. You can specify more than one column to group by. Generally the same as the 'cols_to_group' parameter in 'calculate_mf' when generating mf_96.
indiv_y	A logical value specifying whether the the max response value for the y-axis should be scaled independently for each group (TRUE) or scaled the same for all groups (FALSE). Default is FALSE.
sum_totals	A logical value specifying whether to display the total sum of mutations in the mutation labels. Default is TRUE.
output_path	An optional file path to an output directory. If provided, the plots will be automatically exported using the graphics device specified in output_type. The function will create the output directory if it doesn't already exist. If NULL, plots will not be exported. Default is NULL.
output_type	A character string specifying the type of output file. Options are 'eps', 'ps', 'tex', 'pdf', or 'jpeg', 'tiff', 'png', 'bmp', 'svg', or 'wmf' (windows only). Default is 'svg'.

Details

The function plots the trinucleotide spectrum for all levels of a given group from the provided mf_96 data; the output of calculate_mf with subtype_resolution = "base_96".

Value

A named list containing ggplots.

Examples

```
# Load example data
example_file <- system.file(
  "extdata", "Example_files",
  "example_mutation_data_filtered.rds",
  package = "MutSeqR"
)
example_data <- readRDS(example_file)

# Calculate the mutation frequency data at the 96-base resolution
mf_96 <- calculate_mf(
```

```

mutation_data = example_data,
cols_to_group = "dose_group",
subtype_resolution = "base_96",
variant_types = "snv"
)
# Plot the trinucleotide proportions for each dose group
# Scale y-axis the same for all groups
plots <- plot_trinucleotide(
  mf_96 = mf_96,
  response = "proportion",
  mf_type = "min",
  group_col = "dose_group",
  indiv_y = FALSE,
  output_path = NULL
)

```

plot_trinucleotide_heatmap

Create a heatmap plot of mutation subtype proportions.

Description

This function creates a heatmap plot of subtype proportions for a given grouping variable. The groups may be faceted by a second variable. Mutation sums for each facet group and normalized subtype are calculated and displayed.

Usage

```

plot_trinucleotide_heatmap(
  mf_data,
  group_col = "sample",
  facet_col = "dose",
  mf_type = "min",
  mut_proportion_scale = "turbo",
  max = 0.2,
  rescale_data = FALSE,
  condensed = FALSE
)

```

Arguments

mf_data	A data frame containing the mutation frequency data at the desired base resolution. This is obtained using the 'calculate_mf' with subtype_resolution set to the desired resolution. cols_to_group should be the same as 'group_col'.
group_col	The variable to group by.
facet_col	The variable to facet by.
mf_type	The type of mutation frequency to plot. Options are "min" or "max". (Default: "min")

mut_proportion_scale	The scale option for the mutation proportion. Options are passed to <code>viridis::scale_fill_viridis_c</code> . One of <code># inferno</code> , <code>magma</code> , <code>plasma</code> , <code>viridis</code> , <code>cividis</code> , <code>turbo</code> , <code>mako</code> , or <code>rocket</code> . We highly recommend the default for its ability to discriminate hard to see patterns. (Default: "turbo")
max	Maximum value used for plotting the proportions. Proportions that are higher will have the maximum colour. (Default: 0.2)
rescale_data	Logical value indicating whether to rescale the mutation proportions to increase the dynamic range of colors shown on the plot. (Default: TRUE)
condensed	More condensed plotting format. Default = FALSE.

Value

A ggplot object representing the heatmap plot.

Examples

```
# Plot the trinucleotide proportions per sample, faceted by dose group.
example_file <- system.file("extdata", "Example_files",
                           "example_mutation_data_filtered.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)
# define dose_group order
example_data$dose_group <- factor(example_data$dose_group,
                                levels = c("Control", "Low",
                                           "Medium", "High"))

mf_96 <- calculate_mf(example_data,
                     cols_to_group = "sample",
                     variant_types = "snv",
                     subtype_resolution = "base_96",
                     retain_metadata_cols = "dose_group")
plot <- plot_trinucleotide_heatmap(mf_96,
                                  group_col = "sample",
                                  facet_col = "dose_group")
```

print_ascii_art	<i>This function prints ASCII art when the package is loaded</i>
-----------------	--

Description

This function prints ASCII art when the package is loaded

Usage

```
print_ascii_art()
```

rename_columns	<i>Map column names of mutation data to default column names. A utility function that renames columns of mutation data to default columns names.</i>
----------------	--

Description

Map column names of mutation data to default column names. A utility function that renames columns of mutation data to default columns names.

Usage

```
rename_columns(data, column_map = op$column)
```

Arguments

data	mutation data
column_map	a list that maps synonymous column names to their default.

Value

the mutation data with column names changed to match default.

render_report	<i>Read configuration file and render R Markdown document</i>
---------------	---

Description

This function reads a configuration file in YAML format, extracts the parameters, and renders an R Markdown document using the specified parameters.

Usage

```
render_report(  
  config_filepath,  
  output_file = "./MutSeqR-Summary-Report.html",  
  output_format = "html_document"  
)
```

Arguments

config_filepath	The path to the configuration file.
output_file	The name of the output file. Will be saved to the outputdir in config params.
output_format	The format of the output file. Options are "html_document" (default), "pdf_document", or "all".

Value

None

reverseComplement	<i>Get the reverse complement of a DNA or RNA sequence.</i>
-------------------	---

Description

Get the reverse complement of a DNA or RNA sequence.

Usage

```
reverseComplement(
  x,
  content = c("dna", "rna"),
  case = c("lower", "upper", "as is")
)
```

Arguments

x	A character vector of DNA or RNA sequences.
content	c("dna", "rna") The type of sequence to be reversed.
case	c("lower", "upper", "as is") The case of the output sequence.

Details

This file is part of the source code for SPGS: an R package for identifying statistical patterns in genomic sequences. sidak	<i>Correct p-values for multiple comparisons</i>
-------	--

Description

Correct p-values for multiple comparisons

Usage

```
sidak(vecP)
```

Arguments

vecP	vector of p-values
------	--------------------

Details

This function corrects a vector of probabilities for multiple testing using the Bonferroni (1935) and Sidak (1967) corrections. References: Bonferroni (1935), Sidak (1967), Wright (1992). Bonferroni, C. E. 1935. Il calcolo delle assicurazioni su gruppi di teste. Pp. 13-60 in: Studi in onore del Professore Salvatore Ortu Carboni. Roma. Sidak, Z. 1967. Rectangular confidence regions for the means of multivariate normal distributions. Journal of the American Statistical Association 62:626-633. Wright, S. P. 1992. Adjusted P-values for simultaneous inference. Biometrics 48: 1005-1013. Pierre Legendre, May 2007

Value

adjusted p-values

signature_fitting	<i>Run COSMIC signatures comparison using SigProfilerAssignment</i>
-------------------	---

Description

Run COSMIC signatures comparison using SigProfilerAssignment

Usage

```
signature_fitting(
  mutation_data,
  project_name = "Default",
  project_genome = "GRCh38",
  env_name = "MutSeqR",
  group = "sample",
  output_path = NULL,
  python_version
)
```

Arguments

mutation_data	A data frame containing mutation data.
project_name	The name of the project. This is used to format the data into required .txt format for SigProfiler tools.
project_genome	The reference genome to use. On first use, the function will install the genome using SigProfilerMatrixGeneratorR::install. e.x. GRCh37, GRCH38, mm10, mm9, rn6
env_name	The name of the virtual environment. This will be created on first use.
group	The column in the mutation data used to aggregate groups. Signature assignment will be performed on each group separately.
output_path	The filepath to the directory in which the output folder will be created to store results. Default is NULL. This will store results in the current working directory.
python_version	The version of python installed on the user's computer.

Details

Assign COSMIC SBS signatures to mutation data using `SigProfilerAssignment`. Data is cleaned and formatted for input into SigProfiler tools. This function will create a virtual environment using `reticulate` to run python, as this is a requirement for the SigProfiler suite of tools. Note that it will also install several python dependencies using a conda virtual environment on first use. Please be aware of the implications of this. For advanced use, it is suggested to use the SigProfiler python tools directly in python as described in their respective documentation. Users must have python installed on their computer to use this function.

Mutation data will be filtered to only include SNVs. Variants flagged by the `filter_mut` column will be excluded.

Value

Creates a subfolder "SigProfiler" in the output directory with SigProfiler tools results. For a complete breakdown of the results, see the Readme file for MutSeqR. Most relevant results are stored in SigProfiler > [group](#) > matrices > output > Assignment_Solution > Activities > SampleReconstruction > WebPNGs. These plots show a summary of the signature assignment results for each group. In each plot, the top left panel represents the base_96 mutation count for the group. The bottom left panel represents the reconstructed profile. Below the reconstruction are the solution statistics that indicate the goodness of fit of the reconstructed profile to the observed profile. (Recommended cosine similarity > 0.9). The panels on the right represent the SBS signatures that contribute to the reconstructed profile. The signature name and its contribution % are shown in the panel. A high contribution means a high association of the signature with the group's mutation spectra.

Examples

```
## Not run:
example_file <- system.file("extdata", "Example_files",
                           "example_mutation_data_filtered.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)
signature_fitting(mutation_data = example_data,
                  project_name = "Example",
                  project_genome = "mm10",
                  env_name = "MutSeqR",
                  group = "dose",
                  python_version = "3.11")

## End(Not run)
```

spectra_comparison	<i>Compare the overall mutation spectra between groups</i>
--------------------	--

Description

`spectra_comparison` compares the mutation spectra of groups using a modified contingency table approach.

Usage

```
spectra_comparison(
  mf_data,
  exp_variable,
  mf_type = "min",
  contrasts,
  cont_sep = "\t"
)
```

Arguments

mf_data	A data frame containing the MF data. This is the output from calculate_mf(). MF data should be at the desired subtype resolution. Required columns are the exp_variable column(s), the subtype column, and sum_min or sum_max.
exp_variable	The column names of the experimental variable(s) to be compared.
mf_type	The type of mutation frequency to use. Default is "min" (recommended).
contrasts	a filepath to a file OR a dataframe that specifies the comparisons to be made between levels of the exp_variable(s) The table must consist of two columns, each containing a level of the exp_variable. The level in the first column will be compared to the level in the second column for each row in contrasts. When using more than one exp_variable, separate the levels of each variable with a colon. Ensure that all variables listed in exp_variable are represented in each entry for the table. See details for examples.
cont_sep	The delimiter used to import the contrasts table. Default is tab.

Details

This function creates an $R \times 2$ contingency table of the subtype counts, where R is the number of subtypes for the 2 groups being compared. The G2 likelihood ratio statistic is used to evaluate whether the proportion (count/group total) of each mutation subtype equals that of the other group.

The G2 statistic refers to a chi-squared distribution to compute the p-value for large sample sizes. When $N / (R-1) < 20$, where N is the total mutation counts across both groups, the function will use a F-distribution to compute the p-value in order to reduce false positive rates.

The comparison assumes independence among the observations, as such, it is highly recommended to use mf_type = "min".

Examples of contrasts: For 'exp_variable = "dose"' with dose groups 0, 12.5, 25, 50, compare each treated dose to the control:

```
12.5 0
```

```
25 0
```

```
50 0
```

Ex. Consider two 'exp_variables = c("dose", "tissue")'; with levels dose (0, 12.5, 25, 50) and tissue("bone_marrow", "liver"). To compare the mutation spectra between tissues for each dose group, the contrast table would look like:

```
0:bone_marrow 0:liver
```

12.5:bone_marrow 12.5:liver
25:bone_marrow 25:liver
50:bone_marrow 50:liver

Value

the log-likelihood statistic G2 for the specified comparisons with the p-value adjusted for multiple-comparisons.

Examples

```
# Load the example data
example_file <- system.file("extdata", "Example_files",
                           "example_mutation_data_filtered.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)

# Example: compare 6-base mutation spectra between dose groups
# Calculate the mutation frequency data at the 6-base resolution
mf_data <- calculate_mf(mutation_data = example_data,
                      exp_variable = "dose_group",
                      subtype_resolution = "base_6")
# Create the contrasts table
contrasts <- data.frame(col1 = c("Low", "Medium", "High"),
                       col2 = rep("Control", 3))
# Run the comparison
spectra_comparison(mf_data = mf_data,
                  exp_variable = "dose_group",
                  mf_type = "min",
                  contrasts = contrasts)
```

subtype_dict	<i>Values accepted for mutation subtypes</i>
--------------	--

Description

These values are used to enable user input to translate to columns in a mut file

Usage

subtype_dict

Format

A vector with corresponding values

subtype_list	<i>A list of mutation subtypes at different resolutions</i>
--------------	---

Description

A list of mutation subtypes at different resolutions

Usage

```
subtype_list
```

Format

A list with corresponding values

write_excel	<i>Write Excel tables</i>
-------------	---------------------------

Description

Writes data to an Excel file.

Usage

```
write_excel(data, output_path = NULL, workbook_name, model_results = FALSE)
```

Arguments

data	A data frame or a list of data frames. If a data frame, it will be written to a single sheet in the Excel workbook. If a list, each data frame will be written to a separate sheet in the Excel workbook. Data may also be the output to model_mf, in which case set model_results = TRUE.
output_path	The directory where the Excel file should be written. Default is NULL, which will write the file to the current working directory.
workbook_name	The file name for the Excel file.
model_results	A logical value indicating whether the data is the output of model_mf. Default is FALSE. If TRUE, the function will grab the model_data, point_estimates, and pairwise_comparisons data frames from the model_mf output and write them to separate sheets in the Excel workbook.

Value

A saved Excel workbook.

Examples

```
## Not run:
example_file <- system.file("extdata", "Example_files",
                           "example_mutation_data_filtered.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)
mf1 <- calculate_mf(example_data,
                   cols_to_group = "sample",
                   subtype_resolution = "none",
                   retain_metadata_cols = "dose")
mf2 <- calculate_mf(example_data,
                   cols_to_group = c("sample", "label"),
                   subtype_resolution = "none")
mf3 <- calculate_mf(example_data,
                   cols_to_group = "dose",
                   subtype_resolution = "base_6",
                   variant_types = c("-ambiguous", "-uncategorized"))
list <- list(mf1, mf2, mf3)
names(list) <- c("mf1", "mf2", "mf3")

# save a single data frame to an Excel file
write_excel(mf1, output_path, workbook_name = "test_single")
#save a list of data frames to an Excel file
write_excel(list, output_path, workbook_name = "test_list")

# save model results to an Excel file
model <- model_mf(mf1,
                  fixed_effects = "dose",
                  reference_level = 0,
                  contrasts = data.frame(col1 = c(12.5, 25, 50),
                                         col2 = rep(0,3)))
write_excel(model,
            workbook_name = "test_model",
            model_results = TRUE)

## End(Not run)
```

write_mutational_matrix

Write a Mutational Matrix to input into the sigprofler web application

Description

Creates a .txt file from mutation data that can be used for mutational signatures analysis using the SigProfiler web application. Can handle group analyses (ex dose, tissue, etc). Currently only supports SBS matrices i.e. snvs.

Usage

```
write_mutational_matrix(
  mutation_data,
  group = "dose",
  subtype_resolution = "base_96",
  mf_type = "min",
  output_path = NULL
)
```

Arguments

mutation_data	The object containing the mutation data. The output of <code>import_mut_data()</code> or <code>import_vcf_data()</code> .
group	The column in the mutation data used to aggregate groups (e.g., sample, tissue, dose).
subtype_resolution	The resolution of the mutation subtypes. Options are "base_6" or "base_96". Default is "base_96".
mf_type	The mutation counting method to use. Options are "min" or "max". Default is "min".
output_path	The path to save the output file. If not provided, the file will be saved in the current working directory. Default is NULL.

Details

Mutations will be filtered for SNVs. Mutations flagged in `filter_mut` will be excluded from the output. Mutations will be summed across the groups specified in the `group` argument.

Value

a .txt file that can be uploaded to the SigProfiler Assignment web application (<https://cancer.sanger.ac.uk/signatures/assignment>) as a "Mutational Matrix".

Examples

```
example_file <- system.file("extdata", "Example_files",
                           "example_mutation_data_filtered.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)
temp_output <- tempdir()
write_mutational_matrix(mutation_data = example_data,
                       group = "dose_group",
                       subtype_resolution = "base_96",
                       mf_type = "min",
                       output_path = temp_output)

list.files(temp_output)
# The file is saved in the temporary directory
# To view the file, use the following code:
## output_file <- file.path(temp_output, "dose_group_base_96_mutational_matrix.txt")
```

```
## file.show(output_file)
```

```
write_mutation_calling_file
```

Write the mutation calling file to input into the SigProfiler Assignment web application.

Description

Creates a .txt file from mutation data that can be used for mutational signatures analysis using the SigProfiler Assignment web application. Currently only supports SBS analysis i.e. snvs.

Usage

```
write_mutation_calling_file(
  mutation_data,
  project_name = "Example",
  project_genome = "GRCm38",
  output_path = NULL
)
```

Arguments

mutation_data	The object containing the mutation data. The output of import_mut_data() or import_vcf_data().
project_name	The name of the project. Default is "Example".
project_genome	The reference genome to use. (e.g., Human: GRCh38, Mouse mm10: GRCm38)
output_path	The path to save the output file. If NULL, files will be saved in the current working directory. Default is NULL.

Details

Mutations will be filtered for SNVs. Mutations flagged in filter_mut will be excluded from the output.

Value

a .txt file that can be uploaded to the SigProfiler Assignment web application (<https://cancer.sanger.ac.uk/signatures/assignment>) as a "Mutational calling file".

Examples

```
example_file <- system.file("extdata", "Example_files",
                           "example_mutation_data_filtered.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)
temp_output <- tempdir()
```

```
write_mutation_calling_file(mutation_data = example_data,
                           project_name = "Example",
                           project_genome = "GRCm38",
                           output_path = temp_output)

list.files(temp_output)
# The file is saved in the temporary directory
# To view the file, use the following code:
## output_file <- file.path(temp_output, "mutation_calling_file.txt")
## file.show(output_file)
```

write_reference_fasta *Write FASTA file of reference sequences.*

Description

Write FASTA file of reference sequences.

Usage

```
write_reference_fasta(regions_gr, output_path = NULL)
```

Arguments

regions_gr	A GRanges object including the sequences of the reference regions included for the data. This can be generated from the <code>get_seq</code> function.
output_path	The directory where the FASTA file should be written. Default is NULL, which will write the file to the current working directory.

Details

Generate an arbitrary multi-sequence FASTA file from GRanges including the reference sequences.

Value

Writes a FASTA reference file "reference_output.fasta". If multiple ranges are included in the GRanges object, the sequences will be written to a single FASTA file. Sequences names will be the seqnames (contig) of the range.

Examples

```
## Not run:
# Write FASTA files for the 20 genomic target sequences
# of TwinStrand's Mouse Mutagenesis Panel.
rg <- get_seq("Tspanel_mouse")
write_reference_fasta(rg, output_path = NULL)

## End(Not run)
```

write_vcf_from_mut	<i>Write mutation_data to a VCF file</i>
--------------------	--

Description

Export your mutation_data to a VCF file for downstream applications.

Usage

```
write_vcf_from_mut(mutation_data, output_path = NULL)
```

Arguments

mutation_data	A data frame of a GRanges object containing your mutation data. This can be the output of import_mut_data, import_vcf_data, or filter_mut. Coordinates must be 1-based. Required columns are "contig", "start", "end", "ref", "alt", "sample", "alt_depth", "total_depth", and "ref_depth". Additional columns are allowed.
output_path	The directory where the VCF file should be written. Default is NULL, which will write the file to the current working directory.

Value

Writes a VCF file of mutations "mutation_output.vcf".

Examples

```
## Not run:
example_file <- system.file("extdata", "Example_files",
                           "example_mutation_data_filtered.rds",
                           package = "MutSeqR")
example_data <- readRDS(example_file)
write_vcf_from_mut(example_data)

## End(Not run)
```
